THE
SYMBOL
OF
SERVICE

WELL-KNOWN to millions of telephone users is the circular emblem of the Bell System. Its importance is not in its plain and simple design but in what it represents. Back of it is the far-flung organization that enables you to talk to almost any one, at any time. It is the mark of a friendly service.

The Bell System consists of twenty-four regional companies, each attuned to the needs of the territory it serves. There is also the Bell Telephone Laboratories, working ceaselessly and scientifically to improve the scope and value of your telephone. There is the Western Electric Company, specializing in the economical production of telephone equipment of the highest quality. Co-ordinating and assisting the

work of the operating companies, Bell Laboratories and Western Electric, is the American Telephone and Telegraph Company. It is owned largely by the people it serves and there are nearly 700,000 stockholders. They represent a cross-section of the American people; they come from every walk of life and live in every state of the Union. No one owns as much as one per cent of its stock.

Everything has been planned and organized for one specific purpose—to give you the best possible telephone service at the lowest possible cost.

A telephone serves you in many ways each day. It runs your errands; takes you to friends and brings them to you; speeds aid in emergency. It does these things and many more—for a few cents a day. The Business Office of your local Bell Telephone Company, or any employee, will gladly take your order.

DENTAL CARIES, Incidence	78.0%	33.7%	83.4%

Dental Disorders Checked by High-Citrus-Fruit Diet

*Complete Details of Mooseheart Work
Made Available to Dentists, Physi-
cians and Nutritionists in New
Monograph—Illustrated in
Direct Color*

THE average American diet appears to be deficient in certain substances requisite to dental health. Gingivitis and dental caries can occur in the majority of a large group of children who are receiving a quart of milk, one and one-half ounces of butter, a pound of vegetables, half a pound of fruit and nearly one egg a day.

The addition of a pint of fresh orange juice and the juice of one lemon leads to a disappearance of most of the gingivitis and about 50% of the dental caries.

Liberal Amount Needed

When the intake is reduced to three ounces a day for one year, these ailments tend to reappear in their former intensity.

These conclusions are announced in "Diet and Dental Health," a monograph reporting a 3½-year study made at Mooseheart by The Sprague Memorial Institute at the University of Chicago.

Continuance of preliminary work on an amplified scale was made possible by the California Fruit Growers Exchange in providing fruit and additional funds. The Exchange also made available to the Univer-

sity of Chicago Press color plates for the monograph, permitting the Special Advance (\$1) Edition to contain the identical illustrations used in the regular \$4 edition.

Nutritionists: Send for Book

Nutritionists and Physicians, as well as Dentists, will find much of the clinical material in "Diet and Dental Health" directed to them. Tables give precise data, such as serum calcium, oral bacteriology, etc., on the children. This permits correlations for various purposes. The Mooseheart research is easily the most comprehensive clinical nutritional study of children on record. As only a limited number of subscriptions for the monograph can be made available at \$1, an early return of the coupon and remittance is urged.

NO SUSCEPTIBLE PERSON NEED HAVE *Scarlet Fever*

THE effectiveness of Scarlet Fever Toxin in the prevention of Scarlet Fever is attested by its increased routine use in hospitals and institutions in most countries of the world. Scarlet Fever immunization has many definite advantages as a routine in institutions. It has been helpful in halting the development of epidemics.

All Squibb Scarlet Fever Products are made under license from the Scarlet Fever Committee, Incorporated. Potency is assured by a triple control. This control includes laboratory tests and clinical trials, approval of the National Institute of Health at Washington, D. C., and by the Scarlet Fever Committee, Incorporated.

Squibb Authorized Scarlet Fever Products include Scarlet Fever Toxin for Dick test and immunization, and Squibb Scarlet

Fever Antitoxin for temporary prophylaxis and treatment.

In addition to its line of Authorized Scarlet Fever Products, the Squibb Laboratories also market a complete line of Council-Accepted Diphtheria Products; Tetanus and Erysipelas Antitoxins; and other biologicals.

GOVERNMENT RULING

ends confusion on bran products

TO PROTECT the buying public, the United States Food and Drug Administration has advised that every package of cereal labeled "Bran" state on the label exactly what it contains. If less than 50% of the cereal is actually bran, the definite percentage should be printed plainly on the carton. If other parts of wheat are included, a qualifying phrase explaining this should be added.

• • •

BEFORE this ruling, it was not easy for the purchaser to distinguish between a cereal that was entirely bran, or all bran with flavoring, and another that was mostly wheat. The disappointment that resulted from this confusion was due to the fact that part-bran products contain only a percentage of the "bulk" in all-bran products.

Kellogg's ALL-BRAN is labeled "ALL-BRAN Deliciously Flavored with Malt, Sugar and Salt"—describing the product fairly and honestly.

Kellogg's ALL-BRAN has won millions of friends because it corrects most types of common constipation safely

and pleasantly. It furnishes the "bulk" needed for normal elimination. ALL-BRAN is also rich in vitamin B and iron.

However, Kellogg's ALL-BRAN is not a "cure-all." Certain types of intestinal disorders should be treated only on a physician's advice. But if you can eat lettuce and other "bulky" vegetables—you can also eat Kellogg's ALL-BRAN to advantage—for its "bulk" is much the same as that in leafy vegetables.

When you buy a bran cereal, read the wording on the package. The facts are there! Get Kellogg's ALL-BRAN. It furnishes "bulk" in concentrated form for satisfactory results. At all grocers. In the red-and-green package. Made by Kellogg in Battle Creek.

Other Kellogg Products with Bran

* Kellogg's Bran Flakes, with other parts of wheat, now contain more than 50% bran.

* Kellogg's PEP contains less than 50% bran and is now labeled "Toasted Wheat with Extra Bran Added."

* These products, while mildly laxative in character, are popular mainly as delicious, healthful ready-to-eat cereals—and are not recommended primarily for the relief of constipation.

High-Citrus Diet Reduces Gingivitis 83%, Caries 57%

Results of 3½-Year Clinical Study of 440 Children

	FIRST YEAR Standard Diet	SECOND YEAR Added Citrus Fruit	THIRD YEAR Standard Diet
GINGIVITIS, Incidence	74.9%	12.4%	60.3%
DENTAL CARIES, Incidence	78.0%	33.7%	83.4%

Results of Conclusive Clinical Nutritional Study Announced to the Professions in Exhaustive Monograph—with Natural-Color Photographs

GINGIVITIS was reduced more than four-fifths and dental caries more than one-half by adding a pint of fresh orange juice and the juice of a lemon to the individual diets of a large group of children who had been receiving a diet at least as good as that of the average American child.

These results were announced at the conclusion of a 3½-year study of 440 children at Mooseheart by The Sprague Memorial Institute, University of Chicago. They are published in "Diet and Dental Health" (University of Chicago Press).

Diets Described

The standard diet (see table) included a quart of milk, 1½ ounces of butter, a pound of vegetables, ½ pound of fruit and nearly one egg a day.

During the second period this daily diet was supplemented with two full-sized (8 oz.) glasses of fresh orange juice with the juice of half a lemon added.

During the third period the amount of fresh orange juice was reduced to three ounces a day. Dental disorders tended to reappear in their former intensity. *Three ounces did not suffice.*

Preliminary dental studies indicated the value of citrus fruits in the adequate diet. So the California Fruit Growers Exchange agreed to furnish fruit and additional funds

to guarantee completion of the work on an amplified scale. The Exchange also supplied color plates for the monograph, permitting the special advance (\$1) Edition to contain the identical illustrations of the regular \$4 edition.

Nutritionists: Send for Book

Nutritionists and Physicians, as well as Dentists, will find much of the clinical material in "Diet and Dental Health" directed to them. Tables give precise data, such as serum calcium, oral bacteriology, etc., on the children. This permits correlations for various purposes. The Mooseheart research is easily the most comprehensive clinical nutritional study of children on record. The offer of monographs at the advance sale price of one dollar expires March 1, 1934. An early return of coupon and remittance is urged. *Copr., 1934, California Fruit Growers Exchange*

The Appraisal Form For City Health Work

NEW, REVISED EDITION ON THE PRESS

Available March 1, 1934

THE Committee on Administrative Practice announces the Fourth Edition of the Appraisal Form for City Health Work.

In the words of its sponsors, the Form is a compendium of practices and activities which represents a sampling of the main elements of a generally desirable municipal health program. Its purpose is to assist the health officer in planning his program and in evaluating his activities.

A comprehensive review of the new edition will be published in the March Issue of this Journal.

A Swift Messenger in Time of Need

TO EVERYBODY there comes, suddenly, the great emergency—the occasion when, regardless of all else, the desperate human need stands first and alone.

To find somebody, to carry word to somebody, to get somebody's advice, to bring somebody quickly, to learn somebody's final answer is for the moment the one, all-important purpose.

Have you ever stopped to consider how great a part the telephone plays in the meeting of such emergencies?

Even our daily routine is a succession of lesser emergencies. Satisfactory living in this complicated world consists largely in grasping situations as they arise, one after another

—solving each promptly, finally, and getting on to the next. We dare not be always just a little too late.

It is because of all this that the telephone is so essential and helpful in the daily life of so many people. To millions of homes it brings security, happiness and the opportunity for larger achievement.

Your home is safer—life moves more smoothly—when you have extension telephones in the rooms you use most. The cost is small, especially when you consider the time and steps saved, the increased comfort and privacy. Installation can be made quickly, at the time you set. Just call the Business Office of your local Bell Telephone Company.

A GRAPHIC PICTURE OF THE RICH IRON-CONTENT OF BRAN

MEASUREMENTS in a leading nutritional laboratory show that bran is a fine source of food-iron. The photograph compares the iron-content of ALL-BRAN with some other foods. A serving of Kellogg's ALL-BRAN (two tablespoonfuls) supplies as much iron as three-quarters of an ounce of beef liver, one egg, a serving of spinach, or one-third cup of raisins.

Other laboratory investigations show that bran—served in proper quantities—furnishes the “bulk” needed for satisfactory laxation. In addition

bran is rich in vitamin B.

Special processes of cooking and flavoring make Kellogg's ALL-BRAN finer, softer, more palatable than ordinary bran. Except in cases of individuals who suffer from intestinal conditions where any form of “bulk” would be inadvisable, ALL-BRAN may be used with safety.

ALL-BRAN may be served as a cereal, or cooked into appetizing muffins, breads, etc. Sold by all grocers. In the red-and-green package. Made by Kellogg in Battle Creek.

THE CITY THAT WAS

By Stephen Smith, M.D.

*Pioneer sanitarian and one of the
founders of
the American Public Health Association*

One of our members said recently that the two following quotations alone were worth the price of the book:

"Cholera was approaching the shores of England. . . . The only known preventive measures were 'flight, fasting and prayer.' The clergy petitioned the Prime Minister to proclaim a day of 'fasting and prayer,' with many expressions of sorrow at the prevailing national vices which had finally provoked the wrath of the Almighty. The Prime Minister replied in substance as follows:

"'Do works meet for repentance. First make your homes and their surroundings clean and wholesome, then you may with propriety ask Almighty God to bless your efforts at protection against the approaching epidemic.'

"The epidemic of 1849 came and went with its apparent usual great disturbances of the people. 'Flight' and 'fasting and prayers' had their natural results, the former being effectual when undertaken in time, and the latter without sensible influence over the mortuary records."

Contrast this old record of health conditions in New York City in 1865 with Professor Winslow's new book "A City Set on a Hill," which presents so dramatically what modern public health practice has accomplished in Syracuse.

Both "Cities" may be purchased through the Book Service. Dr. Smith's book is \$1.00 and the fascinating book of the Syracuse Health Demonstration is \$3.00.

Alum Toxoid Protects 99% in school group

Bulletin Washington State Department of Health:

" . . . A demonstration of the value of alum precipitated toxoid has just been completed in School District # 15, Snohomish County.* A group of 220 Schick positive children and adults were each given a single injection of $\frac{1}{2}$ c.c. alum precipitated toxoid. No severe reactions were reported. Only a few showed localized areas of redness. The small lump or swelling at the site of injection was in no case objectionable and gradually disappeared.

" 200 of this group were again given Schick test seven weeks after injection of the alum precipitated toxoid. 99% showed immunity. Two showed only very slight positive Schick reactions.

" This demonstration apparently substantiates the claim that alum precipitated toxoid is superior as an immunizing agent against diphtheria to the older products. We recommend this preparation for immunizations."

* 160 of this group were immunized with Cutter Alum Toxoid.

Code		Price

SIXTH EDITION

STANDARD METHODS OF MILK ANALYSIS

Now Available

The Chemical Methods for the Analysis of Milk have been revised to conform to the latest revision of the official methods of the Association of Official Agricultural Chemists. Methods for testing milk and ice cream are included.

Methods for the determination of available chlorine in preparations used for sterilizing milk equipment and utensils have also been included.

Five new sub-divisions appear in the Bacteriological section. These include tentative methods already being followed in many milk control laboratories.

The first of these sections deals with the detection of organisms of the *Escherichia-Aerobacter* group. Methods for determining the sterility of milk bottles, cans and other dairy utensils, methods for detecting the presence of thermophilic, psychophilic and saccharophilic bacteria, methods for detecting hemolytic streptococci and methods for examining ice cream are also included.

The sections discussing the standard agar plate technic, the microscopic agar plate technic, the microscopic method of counting bacteria, the methylene blue reduction technic and the sediment test have been completely rewritten and the material reorganized.

In view of the extensive alterations and additions, it is urged upon those who depend upon Standard Methods of Milk Analysis of the American Public Health Association that they discard the Fifth Edition published in 1927 in favor of the new.

"YOU'RE CONNECTED!"

SMILING, the installer takes his leave. He's been courteous, careful, quick. He knew just where the telephone should go. How to place it so that nothing should be marred. And now — "You're connected!"

A few days ago, having a telephone in this house was only an idea. Now it is a reality. Tonight Mother can visit with her friends, talk to relatives miles away, call the doctor should he be needed.

A new neighbor has been linked with the millions of other telephone equipped homes that make America one neighborhood. Another household has discovered the security and convenience brought by the Bell System's unified service of communication.

Those who already have telephone service can save many steps each day by having extensions placed in those rooms most frequently used. Greater convenience, greater privacy, at small extra cost. Call the Business Office of your Bell Telephone Company.

BRAN IS A GOOD SOURCE OF VITAMIN B

LABORATORY measurements show that one ounce of bran furnishes forty-five vitamin B units. Above, you see a pictorial comparison of the vitamin B (B_1) content of ALL-BRAN with some other foods. A serving of ALL-BRAN (two tablespoonfuls) provides as much vitamin B as an apple, a tomato, a carrot, half a glass of orange juice, or a large serving of lettuce.

The vitamin B in bran, together with the generous "bulk" content of this cereal, aids elimination. In addition, bran is rich in iron.

Special processes of cooking and flavoring make Kellogg's ALL-BRAN finer, softer, more palatable than ordinary raw bran. Except in cases of individuals who suffer from intestinal conditions where any form of "bulk" would be inadvisable, ALL-BRAN may be used with safety.

There are many tempting ways to enjoy ALL-BRAN. As a cereal, with milk or cream. Or cooked into fluffy bran muffins, breads, etc. Sold by all grocers. In the red-and-green package. Made by Kellogg in Battle Creek.

EXAX BURETTES FOR EXACT WORK—

RETEMPERED ~ RETESTED

The name "EXAX" on a burette is your assurance of quality and accuracy. This Kimble trade-mark—appearing on Kimble Graduated Glassware—stamps the burette as commercially exact and dependable for all industrial, scientific control and analyses.

OUTSTANDING FEATURES

1. Made from automatic-machine-made tubing of very uniform bore.
2. Straight, thick-walled, and free from blisters, stones and striae.
3. Retempered (strain-free) in special lehr or oven.
4. Carefully calibrated at 5 points at 20° C. Lined and numbered by automatic machines.
5. All lines and numbers deeply acid-etched. Filled with durable blue glass enamel, fused-in.
6. Main division lines completely encircle tube.
7. Stopcock barrels sealed directly to burette tubes for increased strength.
8. Delivery stems cannot trap air. Lower end of stems drawn to gradual taper. Tip openings gauged to deliver liquid accurately.
9. Rubber washer on end of stopcock plug prevents slipping, loss and breakage.
10. Stopcocks accurately ground and tested against vacuum of 15" of mercury.
11. Every burette is retested to these tolerances:—

10 ml	±0.04 ml
25 ml	0.06 ml
50 ml	0.10 ml
100 ml	0.20 ml

Exax Burettes—like every other piece of Kimble Laboratory Glassware—are fully guaranteed by Kimble for performance and workmanship. Stocked by leading Laboratory Supply Houses throughout the United States and Canada.

Latest on Milk FREE

TO any public health officer, any hospital superintendent, any Pediatrician, any state veterinarian, or any university library, or that of a medical school, **CERTIFIED MILK**—the "official magazine" of the American Association of Medical Milk Commissions and the Certified Milk Producers' Association—will, on request, be sent regularly without charge. All you have to do is ask, on your official stationery, that the magazine be mailed to you.

Thus you get, **FREE**, latest information of developments in scientific control of the nutritional content of cows' milk, reports on latest improvements in methods of handling milk, and data on progress in advertising, selling and distribution of milk. Address your request for the magazine to

Sixty-Third Annual Meeting

September 3-6

Pasadena, California

The excellence of the scientific program of the Annual Meeting of the American Public Health Association is the magnet that attracts its distinguished audience.

Read the tentative program for the Pasadena sessions in the July issue of the American Journal of Public Health. Note the compelling worth of its many topics and the professional importance of its contributors.

Add to these fundamentals for a successful meeting this year, the beauty and charm of location both in time and space, the interesting arrangements made for group travel, the sincerity and enthusiasm of our hosts, and you have the formula for an Annual Meeting that cannot be improved upon.

In addition to the program, the July Journal will carry hotel and travel information and much about the meetings of the allied groups, the Health Education Institute and other anticipated features of the Annual Meeting. Hundreds of public health workers throughout the United States and Canada will vacation in California this year, combining attendance at the Annual Meeting with pleasure, recreation and sightseeing.

Will you be among them?

BRAN IS A GOOD SOURCE OF VITAMIN B

LABORATORY measurements show that one ounce of bran furnishes forty-five vitamin B units. Above, you see a pictorial comparison of the vitamin B (B_1) content of ALL-BRAN with some other foods. A serving of ALL-BRAN (two tablespoonfuls) provides as much vitamin B as an apple, a tomato, a carrot, half a glass of orange juice, or a large serving of lettuce.

The vitamin B in bran, together with the generous "bulk" content of this cereal, aids elimination. In addition, bran is rich in iron.

Special processes of cooking and flavoring make Kellogg's ALL-BRAN finer, softer, more palatable than ordinary raw bran. Except in cases of individuals who suffer from intestinal conditions where any form of "bulk" would be inadvisable, ALL-BRAN may be used with safety.

There are many tempting ways to enjoy ALL-BRAN. As a cereal, with milk or cream. Or cooked into fluffy bran muffins, breads, etc. Sold by all grocers. In the red-and-green package. Made by Kellogg in Battle Creek.

ORGANIZED TO SERVE YOU WELL

SEVEN hundred and fifty thousand people own the Bell System. Two hundred and seventy-five thousand operate it. Everybody uses it.

The Bell System is devoted to the task of giving to the American people the best possible telephone service at the lowest cost consistent with financial safety.

It is a big system for it serves a big country.

It is one organic whole — research, engineering, manufacture, supply and operation.

In the conduct of the business, responsibility is decentralized so that the man on the spot can act rapidly and effectively.

At the same time, from company or system headquarters, he is within instant reach of skillful advice and assistance as well as material and supplies.

The Bell System means one policy, one system, universal service — operating for your needs with skill, speed and courtesy.

The "hot metal" department, or blow-shop, where the fabrication of a Kimble Cylinder begins; the glassblower inserts the molten glass into a water-cooled potted mold, blows it into shape, and then fashions the base by hand. Only highly skilled artisans, with years of glass-blowing experience to their credit, are employed by Kimble.

KIMBLE QUALITY IS CONSTANT

Every step in the manufacture of Kimble Blue Line Exax Glassware is performed by master craftsmen who have devoted many years to doing one thing faultlessly. At every step in the process of making a piece of Kimble glassware, the same care, the same expert knowledge and experience as employed by the man in the blow-shop, are built into the products.

It is this great attention to detail—this honesty of purpose and sincerity of workmen and company alike—that have made Kimble Blue Line Exax Glassware what it is and what it stands for today—"Assured Accuracy" in the great laboratories of the industrial, clinical and scientific world.

BRAN SUPPLIES NEEDED "BULK" FOR THE DIET

FRUITS and vegetables — and bran — are the best sources of "bulk," which helps promote elimination. But tests show that certain individuals have much of the fiber of fruits and vegetables broken down in the alimentary tract. When bran is added to their diet, elimination becomes regular again.

Laboratory investigations indicate that bran is a safe laxative food for the average person. Microscopic examination of the intestines of bran-fed laboratory animals, over a period corresponding to 30 years of human

life, failed to show any sign of injury to the intestinal tract.

Special processes of cooking and flavoring make Kellogg's ALL-BRAN finer, softer, more palatable. Except in cases of individuals who suffer from intestinal conditions where any form of "bulk" would be inadvisable, ALL-BRAN may be used with safety.

This delicious ready-to-eat cereal is likewise a good source of vitamin B and iron. Sold by all grocers in the red-and-green package. Made by Kellogg in Battle Creek.

Of smallpox, the Public Health Service* states "no other disease which is reported to the Public Health Service shows such notable reduction in incidence during the period covered" (1928-32). Low incidence often breeds indifference on the part of the public and results in a decreased number of vaccinations. This may in turn increase the possibility of a new flare up of smallpox unless the indifference is overcome.

Happily, thousands of physicians and Public Health Officers are continuing to vaccinate contacts, enforce isolation and educate school boards to the necessity of compulsory vaccination.

*U.S. Public Health Report, Vol. 46—No. 11, March 17, 1933.

The House of Squibb plays an important part in helping the medical profession in its fight against this disease. Smallpox Vaccine Squibb is a highly potent, glycerinized vaccine, prepared with strictest aseptic precautions. It is not released for the market until it has been shown to be capable of producing 100% successful vaccinations in previously unprotected individuals.

Smallpox Vaccine Squibb is dispensed in packages of 1, 5, and 10 capillary tubes, supplied with a rubber bulb and sterile needles for each vaccination.

NOTE: To ensure proper "takes" Smallpox Vaccine should be kept under refrigeration as its potency rapidly diminishes at room temperature.

Each Kimble Blue-Line Exax Centrifuge Tube is carefully retested by skilled operators, after all operations have been completed. The retesting methods employed were adopted only after thorough study and painstaking investigation by the Kimble Research Staff.

KIMBLE Blue-Line Exax Centrifuge Tubes are made with the same exacting care and high quality of workmanship that characterize all Kimble scientific glassware.

SOME NOTEWORTHY FEATURES

1. Tubes closely sorted to have the maximum practical wall thickness.
2. Necks reinforced with machine-tooled finish much stronger than the ordinary flare.
3. Tapers on tubes with conical ends are carefully shaped.
4. Calibration lines are acid etched and filled with a durable blue glass, fused into the lines.
5. Every tube is retempered (strain-free) in a special lehr or oven.
6. Individually inspected to insure freedom from defects and retested to assure accuracy.

For accuracy and assurance, standardize on Kimble Blue-Line Exax Glassware. It is stocked by leading Laboratory Supply Houses throughout the United States and Canada.

PYREX PETRI DISHES

BRAND

PYREX Brand Petri Dishes, introduced in 1931, have reached a volume of sales that now permits a substantial reduction in price. And, in addition, the rims of all PYREX Petri Dishes are now beaded and reinforced by a fire-polishing operation which materially *increases* their strength. These dishes have been widely adopted for increased efficiency and economy in laboratory work, because—

They are more transparent than fine plate glass.

They remain clear after repeated sterilizations.

Tops and bottoms are interchangeable.

They resist scratches and breakage, as well as heat shocks and chemical action.

Their strong, rugged construction with reinforced edges means long life under extremely hard usage.

PYREX Petri Dishes that formerly sold at 50c per pair are now priced at 38c, with corresponding reductions for quantities, as follows:

CATALOG ITEM NO. 1345		Quantity per pkg.	Net Price Each	NET PRICE PER PKG.			
Code Word	Size mm.			1 Pkg.	25 Pkgs.	50 Pkgs.	100 Pkgs.
BEDIM	100 x 15 (Complete)	72	\$.38	\$24.62	\$23.39	\$22.16	\$20.93
BEDKI	Cover only	144	.19	24.62	23.39	22.16	20.93
BEDME	Bottoms only	144	.19	24.62	23.39	22.16	20.93

NOW, for greater efficiency, economy, and enduring satisfaction, standardize on PYREX Petri Dishes. Sold by leading laboratory supply houses throughout the United States and Canada.

Experience with 15,000 young adults —demonstrates that no individual need have Scarlet Fever

DR. GLADYS H. DICK in a recent article* reports the results of tests made of 15,000 young adults for susceptibility to Scarlet Fever. The tests made in four colleges and a number of training schools for nurses showed that an average of 32 per cent. of the individuals tested were susceptible to Scarlet Fever.

None of those showing spontaneous negative skin tests developed the disease, which was epidemic at the time in three of the colleges and two schools of nursing. On the other hand, 341 cases of Scarlet Fever occurred in persons who had not been immunized, not tested—or who had refused immunization. Immunization carried to the point of negative skin reaction gave immunity, which

was retained for a considerable period.

The results of these tests indicate that Scarlet Fever immunization has many definite advantages as a routine in institutions. They show that no individual need have Scarlet Fever—nor any school have an epidemic of the disease.

All Squibb Scarlet Fever Products are made under license from the Scarlet Fever Committee, Incorporated. Potency is assured by a triple control. This control includes laboratory tests and clinical trials, approval of the National Institute of Health at Washington, D. C., and by the Scarlet Fever Committee, Incorporated.

Squibb Authorized Scarlet Fever Products include Scarlet Fever Toxin for Dick test and immunization, and Squibb Scarlet Fever Antitoxin for temporary prophylaxis and treatment.

MORE IMPORTANT THAN ANY MATERIAL THING

MORE important than millions of telephones and millions of miles of wire is the fundamental policy of the Bell System. It is founded on a spirit of fair dealing with the public, with employees and with those who have invested their money in the business.

• • •

"The fact that the responsibility for such a large part of the entire telephone service of the country rests solely upon this Company and its Associated Companies also imposes on the management an unusual obligation to the public to see to it that the service shall at all times be adequate, dependable and satisfactory to the user. Obviously, the only sound policy that will meet these obligations is to continue to furnish the best possible telephone service

at the lowest cost consistent with financial safety. This policy is bound to succeed in the long run and there is no justification for acting otherwise than for the long run. . . .

"Earnings must be sufficient to assure the best possible telephone service at all times and to assure the continued financial integrity of the business. Earnings that are less than adequate must result in telephone service that is something less than the best possible. . . . The margin of safety in earnings is only a small percentage of the rate charged for service, but that we may carry out our ideals and aims it is essential that this margin be kept adequate. . . . This is fundamental in the policy of the management."

Quoted paragraphs are from an address by Walter S. Gifford, president of the American Telephone and Telegraph Company, at Dallas, October 20, 1927.

BRAN SUPPLIES THE "BULK" THAT MANY MEALS LACK

THE average American menu often has too little "bulk"—needed to aid elimination. This "bulk" is furnished in convenient form by bran.

Microscopic examination of the intestines of bran-fed laboratory animals, over a period corresponding to 30 years of human life, failed to show any sign of injury to the intestinal tract.

Special processes of cooking and flavoring make Kellogg's ALL-BRAN finer, softer, more palatable than

ordinary raw bran. Its "bulk" is much like that of leafy vegetables. Except in cases of individuals who suffer from intestinal conditions where any form of "bulk" would be inadvisable, ALL-BRAN may be used with safety.

Kellogg's ALL-BRAN is also a good source of iron and vitamin B.

Kellogg's ALL-BRAN may be enjoyed as a cereal or in cooked dishes. Sold by all grocers. In the red-and-green package. Made by Kellogg in Battle Creek.

Grinding the stopcocks of Kimble Burettes is an important hand operation performed by the highest type of skilled artisan. All Kimble stopcocks are accurately ground and tested against a vacuum of 15" of mercury.

MANY hands are needed to perform the delicate and accurate operations required to produce Kimble Exax Blue Line Graduated Glassware. Nothing short of perfection is good enough. Men skilled and trained through years of glassmaking experience are employed continuously performing the complicated steps necessary to join the various sections of a piece of scientific glassware into a complete unit. The finished article must be free of flaws and blemishes.

The result of Kimble's painstaking attention to detail and workmanship is that when burette or pipette or any other piece of Exax Blue Line Glassware reaches the laboratory there is no doubt about its quality, strength and accuracy. Standardize on Kimble's—for assurance!

Permanent Value of Major Walter Reed's Work on Yellow Fever*

FREDERICK F. RUSSELL, M.D., F.A.P.H.A.
*International Health Division, The Rockefeller Foundation,
New York, N. Y.*

I WISH to thank the officers of the American Public Health Association for the honor they have done me in inviting me to present a paper on Walter Reed's work in yellow fever. It is a particular pleasure for me to do this because as a junior medical officer in the medical corps of the army I had the privilege of knowing Walter Reed personally. To be sure, our relations were such as you would expect between a distinguished senior officer and a rather green lieutenant. I look back with pleasure to the acquaintance, and I shall always remember his friendly way of being helpful to the younger men in the medical corps of the army.

It was in October, 1900, at Indianapolis, Ind., that Walter Reed¹ presented a preliminary report before this Association, describing the work carried out up to that time by the army yellow fever board, which included in its membership, in addition to Walter Reed, James Carroll, Aristides Agramonte, and Jesse W. Lazear.

In this preliminary report Reed first disposed of the *Bacillus icteroides* of Sanarelli, by showing that neither in blood cultures from 18 patients nor at autopsies of 11 cases was this bacillus to be found. The second part of the paper deals with the mosquito, *Aedes aegypti* (known formerly and mentioned by Reed, as *Culex fasciatus*), as the intermediate host of the parasite of yellow fever.

Reed was fully aware of the hypothesis of Carlos Finlay² of Havana, but was unconvinced by his ingenious discussions. In fact, Reed states: "We believe that he has not as yet succeeded in reproducing a well-marked attack of yellow fever within the usual period of incubation of the disease, attended by albumen and jaundice, and in which all other sources of infection could be excluded."

Reed was, on the other hand, greatly influenced by the work of Surgeon Henry R. Carter,³ U. S. Public Health Service, who studied cases of yellow fever at Orwood and Taylor, two neighborhoods in rural Mississippi. Carter observed that it was quite safe for friends to visit a house for a period of 2 or 3 weeks after the development of

* Presented at the Special Memorial Session to Dr. Walter Reed and His Associates on the Yellow Fever Commission at the Sixty-second Annual Meeting of the American Public Health Association in Indianapolis, Ind., October 11, 1933.

the first case of yellow fever in the house, but very dangerous to visit the house after that time. In other words, the house did not become infected until 2 to 3 weeks after the arrival of the patient in the house. Carter called this the period of extrinsic incubation, in contrast to the incubation period of the disease of 1 to 7 days in the person contracting it.

This extrinsic incubation period suggested to Reed the probability of an insect carrier, such as has been found by Sir Ronald Ross in malaria. In the preliminary note presented at Indianapolis he reported 2 positive cases of yellow fever caused by bites of the *Aedes aegypti*, with the usual period of incubation and in which other possibilities of infection could be excluded. The paper is short, concise, and clear, and will well repay the trouble of reading it again.

It is interesting that 33 years later, as one studies Reed's paper, one finds that nothing has to be changed. Much has been added to our knowledge of yellow fever, particularly since 1927, but nothing has had to be taken away from the findings and conclusions embodied in the paper; and this demonstrates, better than anything I can say, the merit and the soundness of Walter Reed's work.

After the Indianapolis meeting Reed returned to his studies in Havana, but while he was still in the United States he made a complete schedule of the experiments to be carried out. These were so arranged that each hypothetical question would be answered by a definite yes or no. This arrangement of the investigation, breaking down the problem into a number of definite hypotheses, each of which can be answered by yes or no, is called by the Germans a "Fragestellung." An examination of Reed's Fragestellung is well worth while, since it is in all respects a model.

In his second paper, read at the Pan American Medical Congress in Havana, Cuba, in February, 1901, Reed was able to present further evidence that the mosquito carried yellow fever, and under what circumstances.

He built a small camp in an isolated place, where he could control absolutely the entire personnel and prevent infection from occurring in the usual way. In this small community of 12 non-immune persons he produced at will 2 outbreaks of yellow fever, the first of 4 cases, the second of 1; and he could limit the number of cases to the number of persons he exposed to the bites of infected *A. aegypti* mosquitoes. The proof that the *A. aegypti* was the intermediate host of the infection was clear and complete.

Following this he showed, as the second necessary step, that the disease could not be propagated in other ways. It had long been the custom of health departments to disinfect houses where yellow fever had occurred, and, of course, every article in the sick room. Quarantine officers were accustomed to disinfect ships, including the cargo and even rocks carried as ballast, and, of course, the passengers' baggage.

Reed determined to test by experimental methods the validity of the common belief that yellow fever was conveyed by fomites. He erected a small house, 14 by 20 feet, with poor ventilation and a rather dark interior but with good screening. In this he placed the soiled linen of patients who had died of yellow fever. Of all classes of fomites, bedding and clothing had always been considered the most dangerous.

In this dark, ill-ventilated room, furnished with soiled bedding and clothing, Dr. R. P. Cooke and 2 privates of the hospital corps slept every night from November 30 to December 19, 1900, a period of 20 days. The experiment was repeated with 2 other non-

immune young Americans for another period of 20 days, ending on January 10, 1901, after additional recently contaminated bedding and clothing had been added. The experiment was repeated a third time with 2 other non-immune young Americans and fresh fomites.

The total period of exposure to so-called infected fomites was 63 days. Seven non-immune persons were exposed, and none of them became infected. Reed's demonstration of the erroneousness of the time-honored doctrine of infectious fomites was immediately accepted by the world.

The third step was to repeat the mosquito work under conditions which could be controlled exactly, and for this purpose he built a second small house, called the infected mosquito building, which was divided into halves by means of a huge screen of wire mosquito netting, extending from floor to ceiling. The only difference between the two rooms was that one contained *A. aegypti* mosquitoes, which had fed on yellow fever patients in the first 3 days of their illness, and the other room did not. Into both rooms he introduced non-immune soldiers; those admitted to the mosquito room contracted yellow fever; those admitted to the mosquito-free room did not. Although the results of the first series of experiments were quite convincing, they lacked what in experimental parlance is called a control. This lack was supplied in the third series by the twin room building, where the conditions were identical on the two sides of the screen, except for the infected mosquitoes on the one side.

One other fundamental experiment was carried out at this time. Reed, Carroll, and Agramonte⁴ produced 4 cases of yellow fever by the subcutaneous injection of blood from yellow fever patients in the first and second days of their illness. This direct method of transfer showed that the infectious

agent was present in the blood, and that mosquitoes added nothing to it, but played a rôle similar to that of anopheles mosquitoes in malarial fever.

This made Reed's conclusions incontestable and convincing to the world, and they have remained true and incontestable to this day. In all the long history of medicine and of natural science there is no better example of the use of the experimental method than this work of Reed and his colleagues. They had shown that yellow fever is carried by *A. aegypti* and that it is not conveyed by fomites.

Reed at this time returned to Washington, but Carroll remained in Havana and studied the effect of filtered blood serum from yellow fever patients. He found that the infectious agent passed through a Berkefeld filter which held back bacteria, and that the infectious agent resembled in this respect the virus of hoof and mouth disease. This was one of the earliest observations on filter passing viruses, and Carroll's findings have been fully confirmed in the past few years.

A survey of the city of Havana had shown that *A. aegypti* was everywhere present in vast numbers, and Reed logically recommended the destruction of these mosquitoes and the protection of the sick against their bites. As a result, all fever hospitals both civil and military were screened, and an anti-mosquito campaign, inaugurated by General Gorgas, the chief medical officer in Cuba, was begun. The campaign was continued and extended, and within a year the disease in Cuba was brought under control, and ultimately eradicated. This closes the first chapter in the modern history of yellow fever.

Reed, having found the method of transmission of the disease, and having recommended a campaign against it based on mosquito control, was recalled to Washington to take up his work at the Army Medical School. As

we look back, we cannot but regret that he did not continue his studies, free from teaching duties. He might have advanced our knowledge and anticipated much of the work of the past decade. What Walter Reed lacked was an experimental animal; he was compelled to use human beings, which greatly limited his experiments. Had he been permitted to continue the yellow fever studies he might have found years ago the animal suited to his needs, and continued his contributions to our knowledge of the disease. As it was, no progress was made from 1901 to 1927.

The second chapter of yellow fever studies begins in 1927 with the discovery by Stokes, Bauer, and Hudson⁵ that the Asiatic monkeys, *Macacus rhesus* and *M. sinicus*, were susceptible to yellow fever and might be used as experimental animals. This finding was the result of a long painstaking search for an experimental animal. Every possible species of West African animal including the chimpanzee was tested, and none of them was found susceptible, a rather interesting and important observation. It was not until the investigators tested the common monkey of the zoological garden, *Macacus rhesus* from India, that they were successful. Now that at last an experimental animal was available it became possible to take up the work where Walter Reed had dropped it. Reed's findings were confirmed and extended.

Although yellow fever in monkeys is usually fatal, nevertheless some of the monkeys that were experimentally infected survived, and they remained immune just as human beings do. Their immunity was shown, (1) by resistance to re-infection, and (2) by the fact that their blood serum would protect another monkey against a fatal dose of the virus. This suggested the possibility of a protection test. Such a test is made as follows: Along with a fatal dose of the virus is given the serum to be tested,

whether of man or monkey. If the monkey survives, the protection test is positive and the donor of the serum must have had yellow fever at some time in the past. The protection test has become the basis for extensive epidemiological surveys, which have permitted later investigators to map out the distribution of the disease in Africa and South America.

As stated, West African monkeys are completely resistant to yellow fever infection. Some of the South American monkeys show evidence of infection but do not develop the symptoms or pathological lesions as completely as Asiatic monkeys. Sawyer and Frobisher⁶ have shown that other animals can develop immune bodies in their serum, although there is no mortality and usually no illness. This is true of the rabbit, ferret, guinea pig, and even the hen. Pettit, Stefanopoulo, and Frasey⁷ showed that immune bodies could be produced in horses, and although they were produced in quantity there was no apparent illness and, of course, no fatalities in this animal.

In 1930, Max Theiler,⁸ then at Harvard, found that a characteristic encephalitis could be produced in albino mice by injecting yellow fever virus directly into the brain, and further that the mouse could be used for the protection test by injecting the serum to be tested together with the virus directly into the brain.

The mouse brain is so small that only the most minute quantities can be injected into it, and for this reason Sawyer and Lloyd⁹ modified Theiler's procedure in an ingenious way. They produced a minimum injury to the brain by injecting into it 0.02 c.c. of a sterile starch solution or other irritant, and then put relatively large quantities of virus and the serum to be tested into the peritoneal cavity. The slight injury to the brain produces a point of least resistance in which the virus is implanted by the

blood stream, and under these conditions the virus increases and the usual encephalitis ensues if the serum is negative; if, however, the mice survive, it is evidence that the person furnishing the serum has at some time in the past had yellow fever. This is now the standard protection test.

Sawyer and Lloyd⁹ made another important observation as to yellow fever virus in albino mice; this is, that not all races of albino mice are equally susceptible, and that satisfactory work can be done only with certain selected strains of such mice, the heredity of the mouse being of great importance.

Walter Reed showed that at summer temperatures *A. aegypti* did not become infective until about 12 days after taking yellow fever blood, and that in the colder weather of the fall the period was prolonged. Bauer and Hudson, working in Lagos, Nigeria, in West Africa, found that the extrinsic incubation period might be as short as 9 days. Davis¹⁰ recently showed that the length of the period is affected by the temperature: at a constant temperature of 37° C. the period is only 4 days; at 36° C. it is 5 days; at 31° C. it is 6 days; at 23 to 25° C. it is 11 days; and at 21° C. it is 18 days. If the mosquitoes were kept at 18° C. they were still unable to transmit the disease after 30 days, but if they were then warmed up to summer temperature they became infective after only 6 days more. We now know that the extrinsic incubation period varies according to the temperature.

Does the virus multiply while in the mosquito? Davis, Frobisher, and Lloyd¹¹ have titrated the virus in the mosquito and have concluded that the virus does not multiply in the insect, but rather decreases in quantity with time, although enough remains so that the mosquito continues infectious throughout life. This is in marked contrast to malaria, in which disease, as we

know, the parasite multiplies enormously in the mosquito. Davis and Shannon¹³ showed that the virus of yellow fever dies with the mosquito and is not transferred to other adults with the ova.

Reed attempted to transmit the disease with one other mosquito, *C. pungens*, but failed. Since we have had experimental animals many other mosquitoes have been studied, and under laboratory conditions no less than 13 new vectors have been found, a result which would not have surprised Reed. He wrote that the subject needed further study. In nature, however, only 2 new vectors have been encountered. In Espirito Santo in Brazil, Soper¹² found a small epidemic of yellow fever going on in the absence of *A. aegypti*, but there were numerous *Aedes fluviatilis* and *scapularis*. *A. aegypti*, however, without doubt, remains the important vector.

PATHOLOGY OF YELLOW FEVER

Councilman,¹⁴ in 1890, studied yellow fever tissues at the request of Sternberg and described accurately the scattered acidophilic hyaline degeneration of parenchyma cells and parts of cells in necrotic areas of the liver, which we now know is characteristic of yellow fever.

Rocha Lima¹⁵ of Brazil first drew attention to the midzonal distribution of the necrosis of the parenchymatous cells of the liver lobule. The cells about the central vein and along the periphery are rarely attacked.

Klotz and Belt¹⁶ describe the changes in the liver as a non-inflammatory necrosis of the parenchyma, unaccompanied by collapse of the tissue or by interstitial hemorrhage, but with more or less cloudy swelling and fatty degeneration. If recovery occurs, there follows regeneration of the parenchyma without fibrosis. Hudson¹⁷ finds the same sequence of events in monkey livers.

Torres¹⁸ of Rio de Janeiro demonstrated the presence of intranuclear cell inclusions in the livers of monkeys. This important observation was confirmed by Cowdry and Kitchen¹⁹ and by Klotz and Belt.²⁰ While the inclusion bodies are found most easily in the livers of monkeys and the brains of mice, they nevertheless can be found in the human liver by careful search.

VACCINATION

The number of accidental laboratory infections was, considering the limited number of workers, very large. We have records of 33 cases with 6 deaths, and the danger was so great that it was imperative that some method of protection be found.

It had been noted that monkeys which received immune serum along with the virus were protected against illness and death. In May, 1931, Sawyer, Kitchen, and Lloyd,²¹ after much preliminary work on monkeys, began vaccinating the laboratory personnel with a serum-virus mixture. Up to the present time, over 100 persons have been immunized without any untoward results, and there has been no further illness among the laboratory personnel.

The present vaccine is therefore successful, but it is cumbersome and costly, and many studies are under way with the object of making it simpler. Some of these studies are quite promising. If the vaccine can be simplified it will be of great help in fighting the disease in infected regions. For example, the entire air personnel could be protected.

DISTRIBUTION OF YELLOW FEVER

The present wide distribution of yellow fever is important and is only now becoming known. So far as we are aware there is no longer any in North or Central America. In South America it is found in northern Brazil, including the Amazon valley, and on the eastern slopes of the Andes in Bolivia. There

is also a small but persistent focus in the interior of Colombia. Although the infected area in South America is extensive, it is constantly diminishing. There are, for example, no longer any foci on the Pacific coast, and it is not unreasonable to expect that if the present campaign is carried out actively for a long enough time the Americas may be freed from the disease.

In Africa, however, the situation is quite different. The area involved is very extensive and the population is huge; in Nigeria alone, there are 20 million blacks living under the most primitive conditions. In Senegal, the Belgian Congo, French Equatorial Africa, Uganda, and the southern end of the Anglo-Egyptian Soudan, are millions of primitive Africans. It will be a long time before the state of civilization and sanitation will make it possible to fight the disease effectively in this region.

A. aegypti mosquitoes can be controlled in the coast towns, however, and the transportation personnel can be vaccinated. Dr. Henry R. Carter believed that West Africa is the real home of yellow fever and that the disease was brought to the Americas by slave ships.

The endemic areas in South America and West Africa were quite harmless to Europe and America until new methods of travel were perfected. Now as new regions are opened up by automobile travel, the disease spreads, and as vast regions are brought close together by the airplane we are again in danger of having yellow fever carried to the Mediterranean and to our own shores.

It behooves us therefore to continue to pursue the study of the disease and its habits of spread, with all the energy possible; to devise better methods of protection than we have had; to develop the practice of vaccination still further; and so to carry on the great work which Walter Reed began in 1900.

Argentina—First National Conference on Neglected and Delinquent Children

THE first national conference on neglected and delinquent children in Argentina was held in Buenos Aires from September 25 to September 30, 1933. It was organized by the National Council for the Welfare of Minors (Patronato Nacional de Menores), a government agency established in 1931 for dealing with the welfare of neglected and delinquent children. The conference was attended by

nearly 100 delegates from various parts of the country. The delegates urged the establishment of one-judge juvenile courts throughout the country and the enactment of uniform child welfare legislation in the various provinces. A bill to carry out these provisions was presented at the conference. It was decided to hold such conferences every two years.—*La Prensa*, Buenos Aires, Sept. 25-Oct. 1, 1933.

X-Ray Mass-Procedure Applicable for the Discovery of Early Tuberculosis in Industrial Groups*

MARGARET WITTER BARNARD, M.D.

*Medical Director, Bellevue-Yorkville Health Demonstration,
New York, N. Y.*

IT has long been recognized in British, European, and American experience that tuberculosis is especially prevalent among industrial workers. Although in some instances this is due to specific occupational hazards, in most cases it is believed that there are a number of factors operating, such as the strain of employment, increasing opportunity for infection through contact, and low wages with a resultant low standard of living. Although the causes are not always clear, the fact remains, corroborated by mortality data, that there is a concentration of tuberculosis among adults in industry, especially in urban areas. This concentration is emphasized in a comparison of 10,000 industrial workers¹ with approximately 100,000 white male policy holders examined by the Life Extension Institute.² Although the gross rates for these two groups are not strictly comparable, the wide divergence in the incidence according to age (Figure I) between the employed males and a large sample of males drawn from the general population, clearly points to the importance of industrial factors in the prevalence of the disease.

Data from a recent survey in New York City³ of 20,000 individuals, most of whom would under normal condi-

tions be found in industrial groups, further confirm the fact of a high tuberculosis morbidity among adults and especially among males. For example (Figure II), in one group of approximately 5,000 white persons surveyed, the yield of definite tuberculosis in the age groups over 20 was from 6 to 10 times as great as for the group below 20 years of age (2.7 to 4.1 compared with 0.4). In all age groups over 30 there was a definitely higher per cent among the males than among the females. The New York survey shows strikingly that the most fruitful place to search for the undiscovered cases of tuberculosis in a community is among the adult population.

How to reach the adult, especially the adult with minimal tuberculosis, and the chronic case, is a difficult problem for the community interested in tuberculosis control. The belief is now generally accepted among those working constantly with tuberculosis, that the disease may not only exist but spread for a considerable period of time before symptoms occur which would cause the individual affected to seek medical care. Therefore, adequate case finding among adults cannot depend upon the individual's presenting himself for examination or medical care, but rather should include the examination of groups of apparently healthy individuals. Industrial groups offer a logical point of

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1932.

attack, but relatively little has been accomplished along this line because of the time and expense involved. Also industrial medical service generally is inadequate for and not adapted to preventive work in tuberculosis.

The ineffectiveness of the usual medical service provided for employee groups as a means of tuberculosis control is illustrated in the case of an industrial organization employing non-factory, semi-skilled and clerical workers. Out of 110 employees referred by this organization to the Consultation Chest Service for Private Physicians* over a period of about 4 years, 51 were found to be tuberculous (Figure III). Of these, 33 or 64.7 per cent were moderately or far advanced. Many of them were sputum positive and had undoubtedly been active sources of infection. Among the causes of the advancement of the disease before diagnosis, there must be considered certain

personnel regulations in this particular group. The men belong to a low income group with a maximum salary of \$2,100. They are allowed 10 days sick leave with pay per year, which, although it is cumulative, is negligible in the care of a chronic disease such as tuberculosis. An absence of 1 year causes them to be dropped from the organization list. No provision is made for assistance to families of sick employees, or for their referral to a suitable agency. Therefore, although the customary medical clinic is maintained for emergencies and illnesses, it is no wonder that an employee will report to it only when seriously ill. Tuberculosis with its insidious onset has every chance to gain headway, and there must be in this group many unknown cases who are actively spreading the disease.

Effective control of tuberculosis, especially in the discovery and care of minimal cases in an industrial group, is illustrated by the experience of the Metropolitan Life Insurance Company⁴

* Department of Health. New York City.

during the past 5 years. In 1927 there were two serious tuberculosis problems confronting the medical department in the Home Office. Even after careful preemployment examinations, there were each year a number of breakdowns from tuberculosis among persons employed from 6 months to a year. Also the proportion of advanced cases among the employees found to have tuberculosis had reached about 50 per cent, although all of these employees had annual medical examinations. It seemed either that there was developing in the group an unusually progressive form of tuberculosis, or that the method of examination—an annual physical examination with intercurrent care in the medical rest room for illness—was inadequate, inasmuch as certain cases escaped detection. In October, 1927, the company attempted to rule out manifest tuberculosis in new employees by including in all preemployment examinations a fluoroscopic examination followed by X-ray when indicated. Beginning in March, 1928, the same

method was added to the annual examination of all employees in an effort to detect tuberculosis, even in the absence of physical signs or symptoms.

This intensive survey resulted in the discovery of a comparatively large number of cases in 1928 (Table I). The

FIGURE III

DISTRIBUTION OF DIAGNOSES AMONG 110 INDUSTRIAL EMPLOYEES REFERRED TO THE CHEST CONSULTATION SERVICE

Department of Health, New York City, Jan. 1, 1930-Aug. 28, 1933.

An even more interesting result has been the shift in the proportion of active cases diagnosed in the minimal and the advanced stages, as represented by the employees unable to work who were admitted to the company sanatorium or placed under the care of their own doctors (Table II, Figure IV). By 1932 the per cent of cases in the minimal stage had increased from the 47 per cent of 1928 to 76 per cent; while the per cent of cases in the advanced stage

had dropped from 53 per cent to 24. The shift has been further emphasized by a change in the type of case admitted to the sanatorium. At present, many of the cases admitted have only X-ray findings with no symptoms or physical signs and the length of stay required in the sanatorium has been markedly decreased. The medical department believes that the tuberculosis problem in the Home Office is at present under control and that there now occurs only the development of the amount of tuberculosis which probably is normal for a group of this type.

The use of the X-ray as an effective screen for discovering tuberculosis in adults, and particularly its efficiency in detecting minimal lesions, is again strikingly illustrated by the findings in the New York City Survey (Figure V). Out of the group selected by X-ray for further study, 558 persons were finally diagnosed in the follow-up clinic as having definite tuberculosis and of these 82.3 per cent were classed as minimal while only 17.7 per cent were moderately or far advanced.

Although the X-ray is accepted as

PER CENT OF NEW CASES OF MINIMAL AND ADVANCED TUBERCULOSIS AMONG "HOME OFFICE" EMPLOYEES REFERRED FOR CARE TO SANATORIUM OR PRIVATE PHYSICIANS, METROPOLITAN LIFE INSURANCE COMPANY, 1928-1932

Based on unpublished data, Medical Department, Metropolitan Life Insurance Company.

the most effective method now available for the diagnosis of tuberculosis in adults, its costliness has previously served as a barrier to any extensive use. In New York City in 1933 an opportunity presented itself to study the use of a new commercial method of mass X-ray procedure* by which individuals may be X-rayed at the rate of 150 an hour at the relatively low cost of \$.75 per person if 500 or more individuals are X-rayed per day. This is accomplished by the use of paper film in roll form in a special cassette box, and a series of synchronized units of procedure.†

The subjects strip to the waist and then put on cotton slips, which do not interfere with the subsequent X-ray procedure and make it possible for them

to wait in large groups without embarrassment. As they file past a typist, seated before a special electrically operated typewriter, each steps on a direct-reading dial type of weighing scale, adjacent to which is an upright standard plainly marked in inches. The typist records on a special card made of lead and cardboard, any data desired, such as name, address, age, sex and name of private physician or organization. This card is handed to the subject who, in turn, hands it to the X-ray operator. These cards can be easily typed at the rate of 3 per minute. The subjects then stand in line waiting to be X-rayed.

The machinery is carefully shielded so that no harm can come to those in line. Two technicians are employed, one to place the subject in position, the other to make the exposure. The radiographic unit consists of a standard X-ray generating equipment and tube, and a new form of magazine cassette designed for very rapid operation.

* Powers X-ray Products, Inc., 205 West 39th Street, New York.

† For illustration of methods of procedure, see Barnard, Margaret Witter, M.D. Paper Films in Chest Radiography, *Med. J. & Rec.*, cxxxvii, 6:251-253 (March 15), 1933.

The cassette holds a roll of paper film 14 inches wide and 150 feet long, sufficient to make 100 radiographs 14 x 17 inches each. Provision is made for changing rolls or reloading in daylight. The cassette contains a suitable mechanism for measuring and feeding successive portions of the paper film into position for exposure, and for placing the intensifying screen in close contact with the sensitized side of the film. But one intensifying screen is used, located on the opposite side of the film from the tube. The cassette is quickly and easily adjustable in height to suit the subject being X-rayed. A quickly adjustable compression band permits the holding of the subject closely against the face of the cassette. This compression band can be moved instantly to bring it to the proper height on the subject. Actuated by the compression band mechanism is a pointer which registers on a dial the thickness of the chest of the subject and indicates to the second operator the proper amount of radiographic energy to use for that exposure. The tube support is linked up with the cassette and the compression band in such a manner that the tube is kept automatically at the height of the middle of the compression band. No time therefore is wasted in adjusting the position of the tube, which is always centered on the vertical median line of the cassette.

For the sake of speed in operation, 3 of the 4 controllable variables, viz: time, distance, amperage, and voltage, have been standardized. The time is usually $3/20$ second (occasionally $4/20$ for very thick chests). The distance from the tube to film is 40 inches. The amperage is 100 milliamperes. The voltage is then changed to suit the chest of the subject and varies from 60 to 80 kilovolts.

By means of this coördinated mechanism, designed to simplify the

necessary operation of changing films and positioning the subject and tube, it is possible for two technicians to X-ray subjects at the rate of 4 per minute. A convenient rate of 150 per hour can be maintained without any difficulty, over a long period of time. This speed of taking X-rays would, however, not be of much value unless the procedures of developing and interpreting could also be carried out with equal speed.

The finished rolls are taken immediately to the plant and developed in the roll form, fixed, washed, dried and rolled on a spool ready for interpretation, and returned to the owners. For interpretation, the roll is placed on a special viewing cabinet, in which the films are properly illuminated through daylight glass. The films are successively turned for viewing, either by hand or by an electric motor. The identification data are imprinted on the films from the typed lead marker, saving considerable stenographic time and bookkeeping. Normal films may be simply checked and passed. Any abnormalities noted may be marked directly on the film. The company furnishes all necessary equipment and personnel and delivers the developed film in roll form to the organization at a set price per capita. The films are practically fireproof and may be filed without hazard, either in the roll or cut into separate sheets. Considerable work has been carried on to establish the technical reliability of the paper films⁵ and it is at present our opinion that they are entirely adequate as a diagnostic screen.

Using this method, an X-ray survey was made in 1933 under the direction of Dr. Shirley W. Wynne, Commissioner of Health of New York City, of approximately 20,000 individuals from families on Home Relief,³ in those areas where, because of the excessively high tuberculosis mortality rates, it was be-

lieved there must be many undiscovered foci of infection. The survey was carried out as one of the work projects for medical and nursing service, under an appropriation by the State Temporary Emergency Relief Administration. The two areas selected were Harlem, where the negro and Porto Rican groups predominate; and Red-Hook—Gowanus and Williamsburg—Greenpoint, in Brooklyn. In these areas the tuberculosis death rates were from 4 to 6 times that for the city as a whole, and the same general conditions prevailed of low economic status, with poor and crowded housing facilities.

The Harlem area was surveyed first, all members, 10 years of age and over, of families on relief lists being asked to report for the examination. Approximately 10,000 individuals were X-rayed in about 6 weeks' time. The developed films were delivered to the Bellevue-Yorkville Health Demonstration, where they were interpreted, cut, and distributed to the follow-up clinics. The reading of the films was completed in about 8 weeks. Cases diagnosed on X-ray as tuberculosis or suspect-tuberculosis were cleared with the city registry, and those not previously known were examined in the follow-up clinics and placed under care. All household contacts, other than those already found negative in the X-ray survey, were asked to report for examination. These contacts were mainly children under 10 years of age, who were tubercu-

lin tested and X-rayed if positive to tuberculin. When this follow-up had been fairly well cleared, the cases were turned over to the official clinics of the district. The second survey of approximately 10,000 individuals was then carried out in a similar manner in Brooklyn.

Besides the cases diagnosed by X-ray as tuberculosis and suspect-tuberculosis, there were discovered a large number of persons with cardiac lesions, and these were also listed for investigation. Table III shows the number and per cent of persons designated by X-ray findings for follow-up work in each area.

Twelve hundred and fifty-four or 12.3 per cent of the 10,232 persons X-rayed in Harlem, and 976 or 9.8 per cent of the 10,000 persons X-rayed in Brooklyn, were diagnosed as having tuberculosis (definite, suspect or healed). In addition, there were 548 persons (5.4 per cent) in the Harlem group, and 204 persons (2.0 per cent) in the Brooklyn group, found to have cardiac lesions. The higher rate of cardiac conditions among the Harlem population X-rayed is due to the very high rate (8.2 per cent) found among the colored.

The marked difference in the two areas in the per cent of persons classified as having suspect tuberculosis (4.9 per cent in Harlem as against 0.9 per cent in Brooklyn) is largely due to a change in the age groups selected for survey. Based in the Harlem experience, it was considered better adminis-

TABLE III
X-RAY SURVEY OF 20,232 INDIVIDUALS (10,232 IN HARLEM AND 10,000 IN BROOKLYN)
IN NEW YORK CITY—1933

X-ray Diagnosis of Cases	Number			Per Cent		
	Harlem	Brooklyn	Total	Harlem	Brooklyn	Total
Total Tuberculosis	1,254	976	2,230	12.3	9.8	11.1
Definite	221	331	552	2.2	3.3	2.7
Suspect	506	92	598	4.9	0.9	3.0
Healed	527	553	1,080	5.2	5.5	5.4
Cardiac	548	204	752	5.4	2.0	3.8

tratively to concentrate the survey on those age groups in which there was the greatest yield of definite tuberculosis (Figure II). Therefore in the Brooklyn part of the survey only persons 15 years of age and over were included.

The astonishingly high percentage of minimal cases among the group finally diagnosed as tuberculosis (Figure V) suggests that we have by this survey probably screened out, while still in minimal form, the moderately and far advanced cases, of 1934 and 1935. Very few of these cases were previously known or were receiving medical care. Most of the individuals did not have symptoms which would have caused them to seek medical aid or to stop work; yet, out of 332 cases finally diagnosed tuberculous in the Brooklyn follow-up clinic, only 14 (4 per cent) needed no further care and 140 (42 per cent), 105 of whom were minimal cases, were recommended for institutional care.

An unexpected by-product of the survey which has aroused considerable interest, because of its public health im-

plications, was the diagnosing of a large number of cardiac lesions by X-ray. Of the entire group of 20,232 persons, 752 were considered from the X-rays to have cardiac pathology. Of these 548 were in the Harlem area and included a large number of persons with aneurysms and other probable luetic cardiac lesions among the negroes. This entire group was referred to the Harlem Health Center for Wassermann tests and, if necessary, to the Cardiac Clinic of Harlem Hospital. The 204 persons in the Brooklyn group who were thought to have cardiac disease were asked to attend the follow-up clinic of the project, and more information is therefore available concerning them. Of this group 157 reported for further examination; 37 were found to be non-cardiac, 7 were in need of immediate hospital care, and 113 needed cardiac clinic care. Only 8 were already under medical supervision, leaving 112 newly discovered cardiac cases for whom care should be arranged. Only 28 were considered to be luetic because of history of infection or a positive blood test.

FIGURE V

558 TUBERCULOSIS CASES CLASSIFIED BY STAGE, X-RAY SURVEY, NEW YORK CITY, 1933

The X-ray survey in New York City demonstrates two prerequisites for preventive work in tuberculosis: where to look for the cases of tuberculosis and a practical and inexpensive technic for use in diagnosis. The results afford convincing evidence of the importance of tuberculosis case-finding among the adult population, and it naturally follows that a significant part of the adult population, especially in urban centers, can best be reached through industrial groups. The X-ray has proved especially effective in the discovery of minimal tuberculosis and the new technic of the rapid X-ray makes it possible to carry the examining procedure to the groups in industrial plants with a consequent minimum expenditure of time on the part of the employees.

The authors state that the 100,924 white males used in this study do not afford a detailed picture of a random sample of the adult white native born population because of the defect of including a disproportionately small number of individuals of the lower economic and social grades; consequently the impairment rates are minimized rather than exaggerated. However, with this fact in mind, the data may be used as the best sample of the white male population for whom tuberculosis morbidity rates are available.

Italian Industrial Welfare Work

INDUSTRIAL welfare work, which is done in Italy by women graduates of the school of social service in Rome, is at present functioning in factories, employing more than 200,000 workers. The welfare work is concerned not only with the workers but also with their families, and in this way it applied in 1932 to about 1,000,000 persons. In that year through the efforts of the

welfare workers 13,000 persons were given physical examinations in their homes or in clinics, 3,500 persons were placed in hospitals or similar institutions, and 3,000 children were sent to the seashore or mountains; advice on family problems was also given in a larger number of cases.—*Assicurazioni Sociali, Rome*, vol. 9, No. 4 (Aug.), 1933.

How Can Public Health Nursing Fit Into a Budget?*

ALMA C. HAUPT, R.N., F.A.P.H.A.

*Associate Director, National Organization for Public Health Nursing,
New York, N. Y.*

WE are here concerned with budgets amounting to 28 million dollars.

This is the amount of money estimated by the National Organization for Public Health Nursing as spent for public health nursing by local agencies, both official and nonofficial, in the United States in 1932. Approximately 15 million dollars were expended by official agencies, and 13 million by non-official agencies. It is further estimated that some 14,300 nurses, exclusive of those in industrial plants, were employed with this amount of money. This estimate is obtained by taking a 5 per cent reduction of the number of nurses in the 1931 census.

Lest these figures swell our heads, we should realize that if nurse distribution were even for the whole country, which alas is not the case, we would have only 1 public health nurse to about 9,000 population. On the basis of the above figures, the per capita cost for public health nursing service is about \$.23, as compared with the minimums suggested by Hiscock in *Community Health Organization* of from \$.79 to \$.86—a long way from this goal.

We deduce also that it costs on an average for all types of agencies \$2,000 to put a public health nurse in the field for 1 year, and we may expect 2,000

hours a year of service from each nurse. This brings us to the realization that each hour of the nurse's time costs the community about \$1.

These figures give us a background for the subject of this paper. For years we have tried to teach the public that health work is essential and that funds must be made available for its support. With varying degrees of success we have roused public interest, but at no time has the support of health work even approached adequacy, and naturally this has a direct bearing on the effectiveness of the service. As we discuss budgets, we must acknowledge our continuous obligation to make our work known and to develop every reasonable resource for increasing budgets. Publicity and money raising are subjects too large to be discussed here, but the need for them deserves emphasis before we come to the present situation revealed by the question "How Can Public Health Nursing Fit into a Budget?"

Today we must arbitrarily limit our subject to a consideration of how to fit our service into a budget that is not only fixed, but below the minimum that we know is essential to good community service. This is the situation of many agencies throughout the country for we know that since the depression some have had budgets reduced anywhere from 10 to 50 per cent; some have had to reduce the number of staff from 5 to 10 per cent; and salaries, the largest

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

item in the budgets, have been reduced an average of 10 per cent with some slashes much heavier. At the same time there has been an unparalleled demand for service, particularly for free home visiting and the free use of clinics.

Let us assume, for purposes of this discussion, that many agencies have gone as far as possible in reducing staffs and salaries, in economies of administration, in using volunteers, and in encouraging the public to support the work. In fact, it is to be hoped that this coming year may see some recovery in size of staffs and salaries. However, the big question today for many agencies still is: "Shall we stretch and thin our service in order to answer every demand made upon us?" or "Shall we make a selection of the types of program to be maintained and a correspondingly careful selection of the types of cases to be carried?"

Whether we consider these questions from the standpoint of the official agency or the nonofficial, we know that our results depend primarily on the ability of our nurses. We are dependent on each individual nurse to make that 1 hour of service worth the \$1 which it costs the community. Recognizing the staff nurse as the pivot around which results center, how can we fail to provide in our budgets those essentials which increase her ability—proper working conditions, salaries above a subsistence level, necessary supervision, and a continuous staff educational program that help her reach her maximum productivity? Obviously here is one of the first requisites of a budget.

As budgets are prepared this fall, many agencies are facing the dilemma of going on with the stretching and thinning process, or of undertaking the selective process. Which shall it be? Believing that many agencies have now stretched and thinned to the point of jeopardizing the very results they try to obtain, let us confine our attention

to this difficult and somewhat bewildering problem of selection. Is it too bold to make the assertion that no agency activity which is unproductive of results justifies a budget? Results are concerned with quantity and quality together with those intangibles we feel through "the human touch."

We must ask then, does an agency doing public health nursing have a right to limit its service? Immediately we recognize that the official agency, supported as it is by taxes, is in a slightly different position from the private agency which earns part of its money and receives the rest from contributions. The official agency has a more difficult task in selection. It must serve the mass of the public and reach large groups of people, because supported by taxes. The private agency is more free to concentrate on service to individuals and families. With these distinctions in mind, let us raise the question in another way, "Is it possible for an agency to say 'No' to a request for service?" An outright "No" may not be tolerated by the public, especially if the "No" comes from the tax supported agency. But there are subtle ways of saying the same "No" and these ways are by the process of selection of both program and cases, and the direction of the nurse's energies where they are most needed. Private hospitals, when their beds are full, turn patients away, refer them somewhere else, or keep the less urgent cases waiting, and the public understands. In the social work field the word "intake" has assumed new significance and "intake" committees and "intake" workers are used to scrutinize each request for service. Many family welfare associations are limiting their cases to those having some deeper social problem than that of relief because relief is becoming more and more accepted as the responsibility of the public agency. We have much to learn from allied fields as

to the necessity for selection and the methods to use in its accomplishment.

We come now to the question "How can selection be made?" No one person, nor the experience of one agency can fully answer it. Each agency must chart its own course by a searching analysis of its records and statistics in relation to the service it offers. There never was a time when exact measurements based on records was so important. Do you know that the results you *think* you obtain are actually substantiated by *facts*? There is new emphasis on the old plea that agencies keep careful records and having kept them, use them constantly for local studies.

One method of selection, perhaps not generally recognized as such, has been the educative trend of agencies to share responsibility for health work with the families served. There has been more effort to motivate families to take care of their own problems; there has been more teaching of nursing skills to members of the family; and more explanation of community facilities which the family may use for itself. In other words, the family today is encouraged to make health decisions for itself, using the health worker as consultant.

A different type of selection, and one which is described here in the hope that it will be discussed, is an adjustment used by the Detroit Visiting Nurse Association.

Faced by the necessity of curtailing service to fit a 40 per cent cut in appropriation from the Community Fund, as of March 1, 1933, the Association decided that a more definite method of reduction must be planned, as to meet the previous 15 per cent cut of January 1, the Association had already trimmed its program. The revised budget showed that approximately two-thirds of the income was from self-support, and one-third from the Community Fund. A weekly analysis from the nurses' daily reports was instituted to see how closely the work followed this distribution of funds. The analysis for February

showed that 50 per cent of the visits were free, 12 per cent part-pay, and 38 per cent full-pay. The staff was told that all sick patients were to receive as much care as they needed, regardless of the fee; that aside from this exception, visits must be reduced among the non-paying patients who were not critically ill and whose family could assume the care. Very careful instructions were given to the staff in order to be certain that this plan was properly interpreted. By March the free and part-pay work represented 58 per cent; it dropped to 50 per cent in April, May, and June, and in July it increased to 57 per cent because in that month the Community Fund increased its appropriation for free and part-pay service.

The weekly visit and fee analysis has proved a useful device in regulating the work to a fluctuating budget. The nurses and supervisors all agree that they have learned the technic of keeping the visit load within the capacity of the available staff.¹

It should be pointed out that it was possible in Detroit to curtail health supervision because of the excellent work done over a period of years by the Department of Health.

Perhaps the best we can do in planning how to make a selection is to try to balance 5 factors which, for purposes of this discussion, we may call "Guides to Selective Service in Public Health Nursing." There is no significance to the order, and all 5 rather than any one will play a part in planning.

1. Concentrate on those services which bring proven results.

The experience of the New York City Health Department in diphtheria control illustrates this point. In 1928 there were in round numbers 11,500 new cases of diphtheria, to which 74,000 visits were made. After the intensive diphtheria control campaign of the Health Department, the 1932 figures were 3,600 new cases to which 27,000 visits were made.² This showed a decrease of 68 per cent in cases and of 63 per cent in visits in a 4-year period. Such figures show definite results of service especially in the lower age groups, and indicate that a job well done in one field may

release nurses for activities in some other part of the program.

2. Meet the most pressing and urgent needs of the community.

How many agencies are analyzing their services according to the most generally accepted quantitative guides so far developed—the *Appraisal Form* of the American Public Health Association and *Community Health Organization* by Professor Hiscock? Are these guides on the desk of every administrator of a public health nursing service?

Do you know the highest death rates and highest sickness rates in your community? What assurance have you that your nursing service is doing its share to lower them? Perhaps some disease or condition formerly needing special attention has been so well controlled that the service given to it can be transferred where the need is greater. This possibility exists unrecognized in many communities and deserves real consideration.

3. Continue those most necessary activities for which the nursing staff is best prepared, and include those new activities for which it is possible to prepare the nurses.

It might be unwise, for example, to attempt an orthopedic service with nurses who had had no special knowledge of this field and for whom no training in this subject was available. Again, results in public health nursing are dependent on the knowledge and skill of the nurses.

4. Develop the services the public has been educated to want and to pay for.

If a community is wide awake to the value of communicable disease control and has never appreciated prenatal care, better results may be expected from continuing the former than from inaugurating the latter during "hard times." The public is expressing itself with a loud voice as to the expenditure of its money. We have spent years teaching the public to want certain

services. Concurrently with fulfilling our obligation to give the public what we have taught it to want, the teaching job must go on. We must interpret new needs and encourage support for the changing values in health work.

5. Know all of the public health, hospital and social service facilities in the community and fit public health nursing into the total community picture.

In Chicago, the Infant Welfare Society was forced to close one of its clinics located in a settlement house in a colored neighborhood.³ The Health Department decided to provide the personnel and management; the Infant Welfare Society gave the equipment; and the settlement house continued the donation of space—a nice piece of interplay between agencies, made possible through knowledge of community facilities and the ability to fit programs together.

These 5 guides, as you can readily see, leave agencies no choice in the keeping of accurate, complete records and in making studies of service. Armed with them, let us put ourselves in the position of those who are conscientiously reviewing those major community health services in which public health nursing plays an important part. How can selection be applied to these services and to the distribution of the nurse's time within each service? Where shall we place our emphasis? and do you agree that the following list is given in the order of importance with essentials first?

1. Communicable disease control including tuberculosis and venereal diseases.

The emphasis is on immunization, case-finding and the teaching of home care and hygiene.

2. Morbidity service, including care of the sick and the correction of defects.

The need of the families of the un-

employed for such service has given fresh recognition to its value. The keynote is careful instruction of the families to give the care, and to use facilities for correction of defects, with the nurse acting in a supervisory capacity until her withdrawal from the case is warranted.

3. Maternity service, including antepartum, delivery and postpartum care.

Here again more teaching of family health is encouraged. Both medical and nursing contacts with prenatal patients are important but their frequency is adjusted to the individual need of the patient and her own ability to understand her problems and to report her own symptoms. In postpartum care, visits the first 3 days are of the greatest significance to the life and well-being of both mother and child, following which normal cases can often be given their actual care by a member of the family whom the nurse may supervise. Home delivery service must be regulated according to the hospital, clinic, and medical facilities of the community, and the cost of that service to the nursing agency.

4. Health supervision.

It is important to reach the early age groups first because studies show that such conditions as malnutrition, tuberculosis, venereal diseases, and others can best be prevented in young children. Thus the order is infant first, then pre-school, school and adult. Here there is very definite opportunity for selection according to the ability of the family to meet its own problem. In some instances group teaching can supplement individual instruction; there can be a better interplay between home and clinic visits with less spacing on a purely routine basis; the appointment system can be used in clinics and is being tried out in home visits; teachers can assist increasingly with the health problem of school children.

Weaving throughout this category—and what category can ever tell the whole story—are two services accentuated by the economic and social problems of the day—nutrition and mental hygiene. These are not listed separately because they are an integral part of every contact the nurse makes with her families.

No agency in the country, official or nonofficial, will find it easy to be selective. The cut is apt to be selective within each service rather than the total elimination of any one service. Certainly it is no credit to us that we have not made these essential services appear vital in our supporting public—Why? Because, for one thing, our house has not been in order. We have cluttered up public health nursing locally with too many agencies. What practical justification is there for any community to have more than 2 agencies employing public health nurses? One would be the official agency, serving both health department and schools; the other, a private agency, would offer bedside care as part of a family health service and experiment in those fields not covered by the official service.

How can Public Health Nursing Fit into a Budget? Our answer is through careful *selection* of services on the basis of study of local needs and local results. To this end there must be close coördination of all agencies and real effort toward combining agencies where possible.

It is through learning to make public health nursing fit the budget we now have that we will see how to plan wisely for the future expansion of budgets which we trust are on their way in these days of national recovery.

Precipitated Toxoid as an Immunizing Agent Against Diphtheria*

J. N. BAKER, M.D., F.A.P.H.A., AND D. G. GILL, M.D., D.P.H.

*State Health Officer; and Director, Bureau of Preventable Diseases,
State Department of Health, Montgomery, Ala.*

THE improvement of toxin or toxoid as an immunizing agent against diphtheria has been the aim of a considerable group of workers in recent years. Ramon,¹ in 1925, found that the addition of tapioca to toxoid improved its value as an antigen and concluded that this improvement was likely the result of slower absorption and slower elimination of the antigen. In 1926, Glenny, Pope, Waddington, and Wallace,² found that the addition of alum to diphtheria toxoid greatly increased its antigenic value. In 1931, Glenny and Barr³ described the complete precipitation of diphtheria toxoid with alum and pointed out that the alum toxoid was slowly absorbed and remained in the body for a sufficient length of time to act as its own secondary stimulus.

In 1930, Havens and Wells, in Alabama, began laboratory experiments in an effort so to perfect an alum precipitated toxoid that one injection would produce immunity. Their findings have been published in previous papers.^{4, 5} Graham,⁶ in 1931, used their product on a group of children in Lee County, Ala., with encouraging results. Graham, Murphree, and Gill,⁶ in 1933, reported further clinical experience with about 96 per cent immunity resulting from a single injection. McGinnis and Steb-

bins,⁷ of Virginia, obtained approximately 95 per cent immunity in a group of 579 Schick-positive children using the Havens' precipitated toxoid, while Massey,⁸ of Maryland, in a group of 93 colored children obtained 98.8 per cent immunity following one injection of this same product. The Director of the National Institute of Health,⁹ following investigation, in a personal communication stated:

We believe that precipitated toxoid is much more active than crude toxoid and that a single dose of 1.0 c.c. is an effective agent. Reactions following its use have certainly been no more noticeable than following crude toxoid; in fact the impression is pretty general that reactions from precipitated toxoid are less frequent and less severe than following the older product. Local induration following precipitated toxoid was observed in a number of cases, particularly following the 1.0 c.c. dose. This induration was in no case objectionable and tended to clear up in about 6 weeks. It is very probable that this local reaction is associated with the large immunity response. We see no reason why Alabama should not adopt this product for general use, and can readily appreciate the great saving in time and expense which will follow.

Supported by these findings the Alabama State Committee of Public Health officially approved this product and adopted it as the standard preparation for use in the state.

This presentation is largely based on additional clinical observations, not used in prior publications, following its use by various county health officers in Alabama, which would seem to sub-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

TABLE I
IMMUNITY STATUS FOLLOWING A SINGLE INJECTION OF PRECIPITATED TOXOID

	Group A Original Schick Positive			Group B No Prior Schick Test		
	Neg.	Pos.	Per Cent	Neg.	Pos.	Per Cent
Under 1	4	0	100	372	0	100
1-6	70	0	100	541	4	99.27
7-12	101	0	100	484	10	97.97
13 Plus	22	0	100	3	0	100
Total	197	0	100	1,400	14	99.01

stantiate further the claim that a more extensive use of the one-dose toxoid for immunization purposes is a scientific and justifiable procedure. Pennsylvania, Maryland, and Arizona State Health Departments, and the City of Pittsburgh, have officially adopted the one-dose toxoid as standard, while other states are experimenting with its use. Several of the leading biological manufacturers now have commercial preparations of alum-precipitated toxoid available.

IMMUNITY

Table I shows the immunity status of a group of children who have been given a Schick test following the toxoid. These Schick tests were done from 6 weeks to 6 months after the inoculation with an average elapsed time of 2-3 months. From this table it is evident that immunity develops quite rapidly and that the younger age groups respond particularly well. These results further corroborate previous reports.

REACTIONS

Table II shows by age groups the total number of children who have been inoculated and whose reactions have been observed. All these children were

given 1 c.c. of the precipitated toxoid subcutaneously. Many of these were given in rural areas under the conditions present in the average field clinic. Boiling of syringes and needles was the usual method of sterilization, but in many instances alcohol was relied upon between irregular boilings.

Precipitated toxoid probably owes much of its efficiency to the fact that it is slowly absorbed from the subcutaneous tissues, and consequently one might expect localized induration lasting 2-4 weeks. In 8 reported cases this indurated area finally suppurated and formed a localized abscess. None of these proved serious, but did require incision. One of these children was suffering from boils at the time of inoculation. The general run of reports from the various health officers would not indicate that the local or general reaction was any more severe than when ordinary toxoid was used. Under "Comments" from field workers the following were typical reports:

"No severe reactions." (1,100 inoculations)

"About a dozen showed localized areas of inflammation, but no suppuration occurred. Seen in larger children rather than infants." (250 inoculations)

TABLE II
TOTAL NUMBER OF CHILDREN INOCULATED

Age Number	Under 1	1-6	7-12	13 Plus	Total
	2,556	10,895	2,691	147	16,289

"No complaints of even mild reactions." (900 inoculations)

"Induration lasting 1-3 weeks. Less general reactions." (1,500 inoculations)

"One rather severe reaction. High temperature—lasted about 4 days." (150 inoculations)

"None." (200 inoculations)

"Average reaction not severe." (1,700 inoculations)

"Reactions in 16 cases; 7 slight redness; 6 redness, swelling and discomfort; 1 no reaction; 2 red swollen area 3 x 2 inches."

"One severe general reaction with chill, temperature 104°. Convulsions beginning about 4 hours after inoculation. Recovery complete." (200 inoculations)

SUMMARY

A single injection of 1 c.c. of precipitated toxoid has rendered 100 per cent of 197 Schick-positive children Schick-negative. Similarly, 1,400 of 1,414

children, or 99 per cent, were Schick-negative when tested on an average of 2-3 months after a single injection. The original immunity status was unknown. Observations on 16,289 inoculations revealed 8 with abscess formation. As a rule local or general reactions were not severe.

Mother's Day in Italy

ANNUAL celebrations of Mother's Day on December 24 were recently ordered by the Government of Italy. These celebrations are to be held under the auspices of the local branches of the National Bureau for the Welfare of Mothers and Children. On that day marriage and birth premiums and premiums to large families will be distributed, and prize competitions will

be held for the best children between the ages of 6 months and 3 years; in addition motion-picture performances will be given for the double purpose of emphasizing the importance of large families and of providing recreation for mothers and children.—*Bollettino degli Atti Ufficiali dell' Opera Nazionale per la Protezione della Maternità e dell' Infanzia*, Rome, Oct., 1933.

Recent Advances in the Chemical Treatment of Sewage*

F. W. MOHLMAN

*Director of Laboratories, The Sanitary District of Chicago,
Chicago, Ill.*

PROGRESS in the treatment of sewage has been marked by the recurrence of cycles in which emphasis is placed either on the biological or the chemical phases. These cycles reflect the human trait of dissatisfaction with things that are, and the desire for new and, possibly, better things. New and different things are not always better and usually they are not cheaper; but the spirit of change and revolt from established usage usually leads to new lines of thought and practice, whether expressed by a "new deal" in economic affairs or by a diversion of attention from biological to chemical methods of sewage treatment.

The great interest shown from 1920 to 1930 in biological processes of sewage treatment, such as activated sludge, aerated colloids and separate sludge digestion, has been transferred during the past 2 or 3 years to methods of chemical treatment of sewage, the use of chemicals for treatment of sludge, and the disposal of such sludge.

This new cycle of interest is so recent, and the actual proven advances are so meager that it is impossible to decide at the present time what permanent contribution to the treatment of sewage will result from the present agitation. Therefore one can only list the work

in chemical fields of sewage treatment during the past few years, point out the obvious accomplishments, and predict with some misgivings the outcome of all of the experimental and promotional activity now under way.

During the past 10 or 15 years mechanical equipment has been introduced into sewage treatment practice in this country on a far more extensive scale than was customary during the preceding 30 years. This use of chemical equipment together with the promotion of the sales of chemicals led to a renewed interest in chemical coagulation, which had flourished in the United States in the decade 1890 to 1900, but waned thereafter and had fallen into almost complete disuse. The history of chemical precipitation has recently been reviewed by Reynolds.¹ A careful study of the literature of sewage treatment and of the patents issued from 1870 to 1900 in England, Germany, and the United States would undoubtedly reveal a prior use or knowledge of most of the coagulants now regarded as new and novel by those interested in the promotion of patented processes. From the standpoint of the technician, however, present chemicals and processes should fairly be judged only with due consideration for the improved knowledge and equipment now available for their use. Likewise the results obtained by chemical treatment with all modern equipment must be compared

* Read at a Joint Session of the Central States Sewage Works Association and the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

with those obtained by activated sludge or trickling filter plants now operating on a large scale. Unfortunately there are no chemical precipitation plants of any magnitude in operation; so results and costs of operation must be based on small-scale or experimental installations, in comparison with long term records of continuous operation of very large activated sludge plants.

TYPES OF CHEMICALS USED

It is difficult to point out new and novel features of chemical coagulants, with one or two exceptions. Chemicals used, or proposed in recent developments, have included the following:

<i>Addition of Coagulants</i>	<i>Addition of Insoluble Solids</i>
Ferric chloride	Paper pulp
Ferric sulphate	Marl
Ferrous sulphate	Cement dust
Lime	Returned sludge
Chlorine	Ground charred sludge
Alum	
Sodium aluminate	<i>Removal of Soluble Solids</i>
Copper sulphate	Zeolite (Chlorine)

The ferric salts are more commonly used now because of their decreased cost, but all coagulants listed, with the possible exception of sodium aluminate and chlorine, were used years ago. The former has not appeared practicable because of its cost, and chlorine has not been effective as a coagulant on sewage although used with some success on packinghouse wastes.

Insoluble solids of all varieties have been used in the past, including clay, ground peat, powdered lignite, flue dust, and chalk. Undoubtedly more materials of similar type could be suggested and used, and theories expounded to claim superior action.

The use of zeolite is apparently new as a means of removal of ammonia and other soluble substances from sewage, although used for many years for removal of ammonia from distilled water

or other liquids in the laboratory. The use of chlorine to fix or precipitate organic matter may also be considered as a new development, although chlorine was suggested many years ago as an oxidizing agent, in the absence of knowledge of its true rôle when applied to sewage and waste liquors.

The flocs formed from the coagulants listed are of varying composition, but in general are

Ferric hydroxide	$\text{Fe}_2(\text{OH})_6$
Aluminum hydroxide	$\text{Al}_2(\text{OH})_6$
Calcium carbonate	CaCO_3
Magnesium hydroxide	$\text{Mg}(\text{OH})_2$
Copper hydroxide	$\text{Cu}(\text{OH})_2$

The completeness of formation of ferric or aluminum floc depends upon the amount of alkali added. If less than the combining proportion of alkali is added the floc will contain some sulphate or chloride, as shown by Miller and others. When sufficient alkali is present the floc is $\text{Fe}_2(\text{OH})_6$. The pH scale is used to determine the completeness of precipitation.

Alum is an expensive coagulant; sodium aluminate is even more expensive.

Inert or insoluble solids weight the floc and facilitate settling. If used in large enough amounts they may aid dewatering of sludge. A small purifying effect may be ascribed to adsorption of soluble ammonia or organic solids.

RECENT CHEMICAL PROCESSES

A brief description of some of the various chemical processes that have been proposed and operated in the past few years will illustrate the widespread interest in this development. The approximate rate of treatment and chemicals used are indicated in Table I.

These processes could be classified in 5 groups, according to the type of coagulation, as follows:

Ferric Hydroxide plus Zeolite
Guggenheim

Ferric Hydroxide plus Insoluble Solids

Laughlin
Lewis
Travers
Putnam

Ferric or Aluminum Hydroxide, plus Chlorine

Diamond Alkali
Stevenson
Streander
Scott-Darcey
Cabrera

Calcium Carbonate plus Magnesium Hydroxide

Landreth
Miller-Koller

Paper Pulp Filtration

Wright

It is believed that this list includes most of the chemical processes that have been investigated during the past few years, although undoubtedly there are others not known to the author.

DEGREE OF PURIFICATION WITH CHEMICAL PROCESSES

A study of the published and unpublished results of most of the processes listed reveals that the degree of purification attainable by practically all of them lies between that obtainable by plain settling and that obtainable by activated sludge treatment.

Based on the results available to the writer, only the Guggenheim effluent

approaches or equals the degree of treatment obtained by the activated sludge plants at Chicago, Milwaukee, or Indianapolis. Coagulation and settling, with or without added materials, gives reduction of B.O.D. ranging from 60 to 75 per cent, based on sewage of average strength; chlorine may boost this 5 per cent. Suspended matter removals vary from 75 to 95 per cent, the higher removal being reached where filters are used. The bacterial efficiency is usually excellent when sufficient chlorine is used or when caustic alkalinity is present.

ACTIVATED SLUDGE RESULTS

A few comparisons are listed in Table II of the results obtained by activated sludge treatment at Milwaukee, Chicago, and Indianapolis, as compared with some of the available data on chemical processes.

These results are the averages of daily analyses of composite samples. The reductions at Milwaukee are highest of the three plants probably because of the strong sewage treated, as compared with Chicago, and the comparatively large amount of air used as compared with Chicago or Indianapolis. The air

TABLE I
CHEMICAL PROCESSES OPERATED IN RECENT YEARS ON SEWAGE

<i>Name of Process</i>	<i>Where Operated</i>	<i>Approximate Volume Treated, gal./24 hr.</i>	<i>Chemicals and Solids Used</i>

used, including channels, was as follows in 1932:

Plant	Air, cu. ft. per gallon
Milwaukee	1.63
Chicago, No. Side	0.43
Indianapolis	0.92

CHEMICAL PRECIPITATION RESULTS

A few results are available to show the reduction of B.O.D. and suspended solids by several chemical processes:

LAUGHLIN

Dearborn—Operation on raw sewage for 26 days, as listed by Zack, with a flow of 1.11 m.g.d. shows 91 per cent reduction of suspended solids and 66 per cent reduction of the 5-day B.O.D. in the unchlorinated effluent. Although daily analyses are made at Dearborn, the plant receives Imhoff sludge from the East Side Treatment Works, which is mixed with the West Side sewage and treated by the Laughlin process. The results obtained on this artificial mixture are not considered representative of what can be obtained on sewage of average strength.

Coney Island—Tests over 11 days at an experimental installation at Coney Island, treating 12,800 gal. per day, resulted in a reduction of 84 per cent of the suspended solids and 69 per cent of the B.O.D. (unchlorinated). Chlorination at the rate of 62 lb. per m.g. increased the suspended solids reduction to 92 per cent and the B.O.D. reduction to 79 per cent.

GUGGENHEIM

Chicago—Results at the North Side Treatment Works in Chicago have not as yet been summarized, but the reduction of suspended solids will average around 95 per cent and of B.O.D. around 90 per cent, on a flow of 25,000 gal. per day.

Results at Dyckman Street in New York were reported by Gleason and Loonam to show 99.5 per cent reduction of suspended solids and 96.7 per cent reduction of B.O.D., on a flow of 2,500 gal. per day.

LEWIS

Atlanta—Operation for 7 days at maximum efficiency, considered as applicable where most exacting requirements are necessary, showed a reduction of 76 per cent of the suspended solids and 77 per cent of the 5-day B.O.D. The amount treated was about 500,000 gal. per day.

TRAVERS

Ashland, Ohio—Tests recently made over a period of 12 days, with an average flow of 500,000 gal. per day, gave approximately 85 per cent reduction of the suspended solids and 50 per cent reduction of the B.O.D.

STREANDER

Streander has claimed that his process will give 75 per cent reduction of the B.O.D. and that the effluent is

"clear and sparkling." The coagulated settled effluent was passed through a sand filter.

STEVENSON

Stevenson stated some months ago that the experiments at Palo Alto indicated that "it will be possible with this type of treatment to effect a removal of 95 per cent of the suspended solids and at least 95 per cent reduction of B.O.D." Chemicals for this degree of treatment were estimated at 250 lb. chlorine and 200 lb. ferric chloride per m.g. Further data in more detail should be submitted to confirm these hopes.

LANDRETH

Although the Winston-Salem plant has been in operation for 7 years, little information of authoritative character is available concerning the removals of B.O.D. and suspended solids. Thrasher in 1929 reported a reduction of 88 per cent of the B.O.D. and 87 per cent of the suspended solids, based upon a so-called "typical analysis" representative of 3 years' operation.

Earlier tests of the Landreth process were reported at Allentown, Pa., in 1926. The process was abandoned later and a new Imhoff tank-trickling filter plant installed and put into operation in 1929.

As an indication of the possibilities in the use of lime to the point of caustic alkalinity, as a precipitant of sewage, experimental tests were made in the laboratories of the Sanitary District of Chicago in 1923. The reduction of 5-day B.O.D. in 11 series of tests at the 39th Street Laboratory averaged 66 per cent and in 12 series of tests at the Des Plaines Treatment Works Laboratory 72 per cent.

CABRERA

Cabrera claimed 89 per cent reduction of suspended solids and 78 per cent

reduction of B.O.D. No detailed results have been published.

OTHER CHEMICAL PROCESSES

Results obtained by the Diamond Alkali Company and the Wright processes have not been reported. It is doubtful whether any representative B.O.D. results are available for the Miller-Koller and Putnam processes. The work by Scott is apparently on an ample scale and the results will be of interest when available.

These comparative results indicate that the recent data on chemical processes are as yet meager and somewhat unconvincing, as compared with the well demonstrated efficiency of the activated sludge process. The preceding conclusion that chemical treatment processes, with the exception of the Guggenheim process, do not equal the degree of treatment of the activated-sludge process, seems to be reasonable and supported by the facts now available.

Some rather loose criticism has been directed against the activated-sludge process because of its biological nature. One of the more imaginative of the statements indicting the biological kingdom was to the effect that:

. . . it is not only a difficult matter to breed, train, and educate microscopic life, but at times impossible to harness and compel these invisible microorganisms to work consistently and continuously, as they are not only structurally delicate but clannish and apparently highly unionized. Food supply and working conditions must be exactly according to their liking or they in a body refuse to work and so obstinate is their nature that rather than work under unfavorable conditions, they prefer to lie down and die, and thereby throw the entire biological machine out of gear.

The results of operation of the larger activated sludge plants hardly support this pessimistic opinion of the obstinacy of microorganisms, which would prefer to go on a hunger strike and die

rather than submit to a daily fare of unpalatable sewage nutriment.

The vagaries of biological life in the activated-sludge process have been exaggerated, in the writer's opinion. While there is considerable literature on "bulking" and occasional instances of inferior operation can be found, the decreased efficiency is usually transitory and monthly average results are not seriously impaired.

SLUDGE DISPOSAL

Sludge produced by chemical processes has several advantages and several disadvantages:

Advantages

1. Usually filters well on mechanical filters.
2. Moisture content of filter cake is usually lower than the moisture content of filtered fresh or digested sludge.
3. If loaded heavily enough with lime, or other inorganic solids, filter cake may not be objectionably odorous.

Disadvantages

1. Dry weight varies from 2 to 3 times the dry suspended solids removed from the sewage, due to the precipitation of inorganic solids, particularly on hard waters.
2. Chemically precipitated sludge generally will not digest satisfactorily.
3. Unless dosed with excessive amounts of lime, chemically precipitated sludge may produce objectionable odors when piled in a heap.
4. As yet no method of disposal of chemically precipitated sludge has been operated successfully on a large scale.

For large plants the most feasible method of disposal of chemically precipitated sludge appears to be by mechanical filtration and incineration. This procedure is inherent in the Guggenheim process, and incineration has been suggested for the Dearborn plant. The sludge from the Wright

vacuum filter at Rockville Center has been incinerated, but this sludge contains a large proportion of paper pulp.

The cost of incineration of chemically precipitated sludge per m.g. of sewage or per capita will probably be greater than that of fresh or digested sludge, because of the excess weight of precipitated solids and the low *B.t.u.* content.

ADVANCES IN CHEMICAL TREATMENT

A comparison of the present development in chemical treatment of sewage with the procedure of three decades ago indicates that we now have more accurate methods of control of coagulation by use of the pH scale and by means of mechanical flocculators; we now have a better measurement of the results of treatment as expressed by the reduction of the biochemical oxygen demand; mechanically-cleaned settling tanks are now used almost universally, whereas their use was formerly quite limited.

New coagulants are better and more effective than the lime and copperas used formerly. Ferric chloride in liquid form is convenient and much cheaper than it was even 5 years ago. A very effective ferric sulphate is now available. Chlorine is used as a germicide with more accurate control than was formerly obtained with chloride of lime.

The use of zeolite for filtration of chemically clarified sewage is an interesting and novel development. It provides a final step which makes it possible to extend the ordinary range of effectiveness of chemical precipitation to what is called complete treatment. The practical value and cost should be demonstrated on a larger scale.

Mechanical filters for coagulated effluents appear to have possibilities for final clarification of the flocculated and settled sewage. A study of costs should

demonstrate whether it is preferable to use such filters with short periods of settling, or whether similar clarification can be obtained at less cost by providing a longer settling period, without operation of final mechanical filters.

Experience over the past 5 years has demonstrated the value of continuous vacuum filters for initial dewatering of sludge. Quite high rates of filtration of chemically precipitated sludge have been obtained recently on the Oliver filters at Dearborn, although not any higher than have been obtained with conditioned sludge at Chicago, Columbus, or Baltimore. Because of the added weight of precipitated solids in the chemical sludge, rates twice as high as those obtained with unprecipitated sewage solids ought to be obtained for equal areas of vacuum filters.

Although filtration on vacuum filters facilitates the initial step in the disposal of chemically precipitated sludge, the filter cake presents the same problem of disposal as was faced years ago at Worcester and Providence. The failure to incorporate incineration of the cake in any of the present chemical processes, with the exception of the Guggenheim, is probably the most unsatisfactory aspect of the recently proposed processes of chemical treatment. Even in the Guggenheim process, drying and incineration has been on too small a scale to demonstrate conclusively the efficiency, cost, and freedom from odor of the incineration procedure.

FIELD OF USEFULNESS FOR CHEMICAL PROCESSES

Chemical coagulation of sewage is practised at a number of plants in England, including Leeds, Barnsley, Dewsbury, and Kingston, where additional clarification is required in excess of that produced by passing the sewage through plain settling tanks. In the United States the increased degree of treatment obtainable with chemicals

has been investigated in a preliminary way at Grand Rapids, Mich., Plainfield, N. J., and Oklahoma City, Okla. Likewise Tatlock at Dayton has claimed a considerable improvement in the degree of treatment in Imhoff tanks by application of relatively small amounts of lime and chlorine, used primarily for odor control.

Such uses of chemicals in existing plants may show more progress in the next few years than the adoption of patented chemical processes. However, there appears to be a need for some cheaper process than activated sludge or trickling filters, in situations where for many months the volume of diluting water is not sufficient for a settled effluent, but more than sufficient for a completely treated effluent. In some cases the presence of a large amount of industrial wastes in sewage may threaten the uniformity of operation of any biological process; in such situations chemical treatment may be indicated. It is possible that the control of chemical processes may be so improved that various degrees of treatment may be obtained by varying the dosage of chemicals. This flexibility of operation has been claimed for chemical treatment, but not much proof of such flexibility is available in the form of long-term operating records.

For the final evaluation of chemical precipitation processes of sewage treatment, many factors require study under careful supervision on a large scale. Among these are the accumulation of operating results and costs and the perfection of chemical control and sludge disposal. Chemical coagulation undoubtedly has a field of usefulness intermediate between settling and complete biological treatment if the problems of control, cost and sludge disposal can be solved by large-scale operation.

Erysipeloid Condition Among Workers in a Bone Button Factory Due to the Bacillus of Swine Erysipelas*

G. FOARD MCGINNES, M.D., DR.P.H., AND FORREST SPINDLE
State Department of Health, Richmond, Va.

SWINE erysipelas, or "diamond skin disease," is primarily a communicable disease of hogs caused by *Erysipelothrix Rhusiopathiae*. Organisms indistinguishable from those found in infected swine have also been isolated from sheep, birds, and fish suffering from a similar condition. The disease was first studied by Pasteur in 1882. He demonstrated a method of immunization by use of an attenuated culture which was obtained by passing the organisms through rabbits, which are relatively resistant to this infection. Some doubt exists as to the purity of the cultures used by Pasteur, and the first complete description of the bacillus of swine erysipelas has been credited to Loefler¹ in 1885. Jensen, in 1891, described a diamond shaped skin lesion in hogs due to the bacillus of swine erysipelas. In 1892, Bang described a verrucose endocarditis caused by this organism. Prausnitz,² in 1921, collected data on approximately 100 cases of human infections with this organism. In the same year Dumont and Cotoni³ described a case of meningitis and isolated a similar organism from the spinal fluid. In 1926, Klauder, Richter and Harkins⁴ published a complete and

accurate description of a number of human infections occurring among New Jersey fishermen. In 1930, Stefansky and Grunfeld⁵ reported 200 cases of infection with bacillus of swine erysipelas occurring among fresh water fish handlers in Odessa. Ingestion of raw sausage made from the meat of swine dying with erysipelas has been reported as causing intestinal infection in man.

During the first 10 months of operation of a bone button factory in Buchanan, Va., 210 cases of erysipeloid occurred among workers in the plant according to information supplied by the plant physician. The clinical study of these cases made by Drs. Lawson and Stinnett⁶ led to the diagnosis of erysipeloid probably due to the bacillus of swine erysipelas.

CLINICAL MANIFESTATIONS

Briefly, the clinical manifestations of the disease were a progressive local swelling, dusky purple discolorization with pain and extreme tenderness of the infected part. There was local heat but no elevation of body temperature. Suppuration was extremely rare, and there was only occasional slight lymphangitis and lymphadenitis. These symptoms appeared usually 3 or 4 days following a superficial injury, usually to an exposed part. The duration of the dis-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 7, 1935.

ease ranged from 9 to 21 days. In approximately 90 per cent of the cases the lesions occurred on the hands. There were 5 cases of severe conjunctivitis resulting from bone dust and 3 cases of severe bronchial infection from the inhalation of bone dust. In 1 case the lesion occurred on the knee following a bruise, and in another the lesion appeared on the foot following laceration by a piece of bone.

EPIDEMIOLOGICAL INVESTIGATION

At the request of Drs. Lawson and Stinnett, an epidemiological and bacteriological study of this outbreak was made in September, 1931, by the State Department of Health. At this time there were 103 white men, 33 white women, and 6 colored men employed in various capacities in the plant. A careful epidemiological and clinical history was taken of each employee. A survey was made of the plant, and each process of operation was studied.

This button manufacturing company formerly operated in Pennsylvania and many of the employees stated that they had had similar infections while working there. The first case in this outbreak occurred about 3 months before the opening of the plant in a person who was engaged to unload the bone, and followed an injury to the foot by a sharp spicule of bone which pierced the shoe. Another case occurred in a person in no way connected with the plant but who used bone meal from this plant as a fertilizer on his garden.

Only adults were employed. Both sexes were affected, but the majority of the cases occurred in males. No women, however, were employed in operations requiring the handling of raw wet bone. Only 6 colored persons were employed, all of whom handled rough wet bone, and among these, 3 had attacks of erysipeloid. The largest number of cases occurred during November and December, but during no season was the plant

entirely free of cases. Fifty per cent of the cases gave a history of a previous attack, frequently on the same hand, indicating that there is little or no local or general immunity produced by an attack.

Cattle and hog bones for use in this plant were obtained from various places, among which were England, Uruguay, Argentina, and Seattle, Wash. The bones were received in carload lots and were well cleaned, though occasionally a little "green" with a slight odor. After reaching the plant they were soaked in large vats of warm water to soften before sawing. Both long and flat bones are used. They are sawed into thin strips on circular power saws, which are kept wet by a stream of water. There is a considerable accumulation of moist bone dust on and around the saws. Between 30 and 60 men are employed in working on the saws, and minor injuries, usually to the hands, are frequent. The thin sheets of bone are carried by hand-truck to the punching machines, which are also kept moist by running water, and there is an accumulation of wet bone dust and fragments of bone on and around the machines. From 50 to 75 men are employed on punching machines, and minor hand injuries are frequent among this group. Six or 8 laborers transfer the bones and the punched buttons to and from the machines. Following the punching of the buttons from the bone they are dried and sent to the sorters and finishers where they are polished, finished, and dyed. Thirty to 50 sorters and finishers are employed and they handle only dried buttons, and injuries are relatively infrequent. Table I shows the attack rate per cent in various groups of workers in the plant.

It may be seen from the tabulation that the infection was correlated with the mechanical occupations of sawing or cutting bones, both occupations requiring the handling of wet bone, and in

TABLE I

ATTACK RATE PER CENT FOR VARIOUS GROUPS OF WORKERS IN THE BONE BUTTON FACTORY

* Injured hand in saw room

both traumatic injuries to the skin are frequent.

BACTERIOLOGICAL CONFIRMATION

At the time of the investigation there were 2 cases of erysipeloid in the acute stage. Both gave a history of having been recently injured at the sites of infection by sharp pieces of bone, 1 below the knee and 1 on the great toe. Sterile normal salt solution was injected into the area around each wound, and a small quantity of fluid was aspirated. Samples of material were also obtained from the following units of operation:

1. Aqueous material from a vat used to soften bone previous to sawing
2. Waste bone material obtained from teeth of saws in a moist state
3. Waste bone material from button punching machines in a moist state
4. Pulverized bone meal sold from the plant for fertilization of soil.

Because of the belief that the original bones might have been the source of infection, samples of bone shipped from Seattle, Uruguay, and Argentina were obtained from shipments before contamination with local material, or

handling could occur. The fluid obtained from the human cases and the various samples taken at the plant were injected subcutaneously into white mice, and guinea pigs were inoculated subcutaneously with vat and saw waste material. Guinea pigs inoculated with bone waste material showed no pathology suggestive of infection with the bacillus of swine erysipelas. Table II shows the results of the mouse inoculations.

An organism identical in morphology and cultural characteristics to bacillus of swine erysipelas was isolated at autopsy from the peritoneal exudate and hearts' blood of mice. These organisms were agglutinated by swine erysipelas serum obtained from Dr. John Buckley, of the Bureau of Animal Pathology, U. S. Department of Agriculture, who also confirmed the identity of the organism isolated from the fluid aspirated in the human case.

SUMMARY AND CONCLUSIONS

Two hundred and ten cases of an erysipeloid condition occurred in a bone

TABLE II
MOUSE INOCULATIONS

Source Material	Number Specimens Examined	Days Survived	Results
Fluid aspirated from human lesions	2	12 Not fatal	Pos. B. swine erysipelas Negative

button factory among individuals handling cattle or hog bones. There was a close correlation with the handling of wet bone and occupations in which injuries were frequent. Repeated attacks of the disease were frequent, indicating that there was little or no local or general immunity produced by an attack. The bacillus of swine erysipelas was isolated from 1 case and from samples of bone, bone material, and bone waste collected at various stages in the manufacture of buttons. For ridding the plant of the

infection we recommend the heating of all bones entering the plant in the soaking vats to a temperature of 144° for at least 2 hours.

Brazil—National Conference on Child Welfare

A NATIONAL conference on child welfare was held in Rio de Janeiro, Brazil, from September 17 to September 27, 1933, under the auspices of the President of the Republic. The work was divided into the following sections: assistance, education, health, medicine,

and legislation. Much time was devoted to a program of urgent child welfare work, which is to be recommended to the authorities for earliest possible consideration. — *Jornal de Brasil*, Rio de Janeiro, Sept. 17-27, 1933.

Arsenic in Tobacco Smoke

C. R. GROSS AND O. A. NELSON

Insecticide Division, Bureau of Chemistry and Soils, U. S. Department of Agriculture, Washington, D. C.

IN some of the tobacco growing sections of the United States, it is necessary to dust the plants with arsenicals during the growing season in order adequately to control insect pests. Lead arsenate is the insecticide most commonly used, but in some cases, particularly with plantings of cigar wrapper tobaccos, Paris green is employed.

Remington¹ apparently was the first to call attention to the presence of arsenic in commercial tobacco products. He found that samples of American pipe-smoking and chewing tobaccos carried arsenical residues ranging from 0.05 to 0.27 gr. of As_2O_3 per lb. (7 to 38.5 p.p.m.). In addition, he reported the hitherto unknown facts that about 50 per cent of the arsenic in the smoking tobaccos was volatilized in the smoke and that about 50 per cent of the arsenic in chewing tobaccos was water-soluble. Inasmuch as Remington devoted his study largely to pipe-smoking and chewing tobaccos, it is believed that the results of similar investigations made by the Insecticide Division on cigars, cigarettes, and smoking tobaccos will be of interest. The description of the smoking apparatus used in making these tests will also be of value.

SMOKING APPARATUS DEvised TO CARRY OUT THE SMOKING TESTS

The apparatus devised to carry out the smoking tests is shown diagrammatically in Figure I. It was operated as follows: In order to imitate as nearly as possible normal smoking conditions, the apparatus was designed to

draw intermittently. This was accomplished by using a small water syphon (S) by which approximately 50 c.c. of air was drawn through the apparatus at each discharge. This air, with its unabsorbed smoke constituents, was prevented from returning into the absorption chambers by means of a check valve (CV), and was discharged into the atmosphere through the Bunsen valve (BV).

The smoke from the cigar, cigarette, or pipe was pulled by the syphon through an absorption train, consisting of two glass tubes about 20 cm. long and 2.0 cm. in diameter, each being constricted to about half the outside diameter at its mid-point. The absorbing material was absorbent cotton, moistened with 5 c.c. 1 per cent NaOH in (B) and 5 c.c. 3.5 per cent HCl in (A). Test runs showed that all the arsenic in the smoke was caught in the tube next to the smoking chamber (SC), but the second tube was retained as an additional safety measure.

The smoking chamber assembly (SC) consisted of a cigar holder, into which could be inserted a cigarette holder (CH) an ash tray (not shown in sketch) placed under the cigar or cigarette, and a glass jacket fitted with a ground glass joint and two side tubes. One side tube was left open for the entrance of air, while the other was connected by a rubber tube to a second absorption train, which in turn was connected to a continuous aspirator. The arsenic in any smoke given off between "draws" was thus absorbed in

this train. In testing smoking tobaccos, the tobacco could either be smoked in a pipe or be made into cigarettes and smoked in this way. In our tests the pipe was used, in which case the smoking chamber assembly was re-

and water was run into the syphon chamber at the rate of about 150 c.c. per minute. As soon as the syphon was functioning properly and discharging at the rate of about 3 times per minute, the cigar or cigarette or pipe was

placed by the pipe assembly (PA), and the tests were carried out thereafter in the same manner as for cigars and cigarettes.

While this apparatus was designed primarily for the determination of arsenic in tobacco smoke, other constituents of the smoke or tar could also be determined by its aid. For example, nicotine could be determined by the method of Waser and Stähle (*Z. Unters Lebensm.* 64:470-85, 1932); pyridine and ammonia by that of Schaarschmidt (*Chem. Ztg.* 56:911-13, 1932); and the compounds in the tarry matter could be ascertained by special methods used in organic analysis. The presence or absence of lead, copper, or fluorine in the smoke could also be easily determined.

METHOD OF MAKING SMOKING TESTS

After the apparatus had been assembled and the absorption tubes charged, a cigar or cigarette or loaded pipe was inserted into its proper holder,

lighted, and the jacket of the smoking chamber was put in place.

When the cigars and cigarettes were smoked down to about $\frac{1}{2}$ " to $\frac{3}{4}$ ", the apparatus was disconnected and the ash, butt and absorbents in both trains were reserved for individual analysis. (In the pipe-smoking tests, the entire pipe load was smoked.) Any tarry matter which had condensed in the holder, was removed with alcohol and added to the absorbents from the lower train, while the tarry substance deposited on the inside wall of the jacket was combined with the absorbents in the upper train.

ANALYTICAL PROCEDURE

All arsenic analyses were made by the method developed by Gross² which eliminates the low results occurring when analysis is made by the Gutzeit method in the presence of undigested residues of the tobacco alkaloid nicotine. In this method the material is digested in the usual manner with nitric

and sulphuric acids, and a suitable aliquot of the diluted solution is made ammoniacal and precipitated with ammonium phosphate and magnesia mixture. The co-precipitated magnesium ammonium phosphate and arsenate is then filtered and rinsed free of interfering nicotine residues, redissolved in hydrochloric acid solution, and analyzed for arsenic by the Gutzeit method, according to the A.O.A.C. procedure.³

QUANTITIES OF ARSENIC IN TOBACCO PRODUCTS STUDIED

Five widely sold domestic brands of cigars, 5 of cigarettes, and 4 of smoking

tobacco were selected for experimentation. Before the smoking tests were conducted, preliminary analyses were made on representative samples of each of the brands to determine the range of arsenical residues present. The analyses were made on analytical units composed of either 1 cigar, 4 cigarettes, or 5 gm. of smoking tobacco. Five such analytical groups were analyzed for each brand studied. The results of these analyses together with those made in the smoking tests reported later were calculated as p.p.m. of As_2O_3 . For general comparison purposes this form of expression was deemed preferable to

4	5.00	34.0	36.0	28.0	32.0	26.0	31.1

calculations made in terms of gr. of As_2O_3 per lb. of sample. Table I shows the amounts of arsenic found in the brands of tobacco analyzed.

The data show a maximum of 48.4, 36.3, and 50.0 p.p.m. of As_2O_3 , respectively, for the cigars, cigarettes, and smoking tobaccos studied. These figures are not conspicuously higher than the maximum of 38.5 p.p.m. found by Remington for arsenic in smoking and chewing tobaccos.

Quite a variation is apparent in the arsenical load carried by individual cigars of the same brand. In cigarettes and pipe tobaccos the variations in arsenical content in any given brand lie within much narrower limits. This is probably due to the mixing such tobaccos receive during the commercial blending process.

DISCUSSION AND RESULTS OF SMOKING TESTS

Analytical units similar to those mentioned above were used in the smoking tests. After smoking either 1 cigar (usually weighing between 6 and 8 gm.), 4 cigarettes (total weight about 4 gm.) or 3 pipeloads of tobacco (adjusted to total 5 gm.), the arsenic was determined in (1) the absorbents of the lower train (containing the arsenic present in the puffed smoke), (2) the absorbents in the upper train (representing the arsenic in the smoke between puffs), (3) the ash, and (4) the butts (except on pipe tobaccos where all the tobacco was smoked).

The results obtained during the smoking tests calculated as p.p.m. of As_2O_3 are given in Table II. Since in all 70 smoking tests were made, and each test for cigars and cigarettes required 4 different analyses, and each on pipe tobaccos 3, the completed data would be too voluminous for expression here. Therefore only the average results from each brand investigated are included in this table.

An exception is made of cigar brand No. 1, which is given in detail, in order to show the method of averaging the data as well as the approximate range of arsenical residues encountered.

All calculations of p.p.m. of As_2O_3 in Table II are based on the original weight of the sample smoked. The totals in the last column agree quite closely with those obtained for the same brands and given in Table I, indicating that the samples tested were representative of the brand.

The data resulting from these smoking tests furnish the opportunity for drawing interesting comparisons between the quantities of arsenic a smoker may inhale and the quantity permitted by law in food products, which is 1.43 p.p.m. (0.01 gr. of As_2O_3 per lb.). The average figures for p.p.m. in the puffed smoke show that a smoker may draw into his mouth the quantity tolerated in 1 lb. of food by the smoking of 1.35 lb. of cigars, 0.56 lb. of cigarettes or 0.16 lb. (about 2.6 oz.) of pipe tobacco. Of course, some of the arsenic is still in the smoke when it is exhaled, and therefore it is different from arsenic in food, in which case the body is exposed to all the arsenic present.

Attention is called to the relatively small quantity of smoking tobacco required to furnish volatile arsenic in the quantity mentioned. Several factors contribute to bring this about. (1) The brands of smoking tobacco tested contained more arsenic than the cigar and cigarette brands. (2) When a pipe is smoked, apparently most of the volatile arsenic is contained in the puffed smoke, due to the dying down of the ember between puffs. In the case of cigars and cigarettes, the amounts of arsenic in the unpuffed and puffed smoke are about equal. (3) All the tobacco was smoked, while with cigars and cigarettes, about 22 per cent was discarded in the butts. (4) A con-

* Samples composed of 1 cigar, 4 cigarettes, or 5 grams of smoking tobacco.

siderable portion of the volatile arsenic is absorbed by or condensed in the butts of cigars or cigarettes. The way in which this fact was demonstrated will

be described later. The pipe smoker who smokes all the tobacco does not therefore have the protection afforded by the butts of cigars and cigarettes.

FORM IN WHICH VOLATILIZED

Whether or not the volatile arsenic in tobacco smoke is free or in combination has not been conclusively determined. From theoretical considerations it is believed that the arsenic is volatilized as As_2O_3 , to which form it has been converted by the conditions of incomplete combustion present during smoking. As_2O_3 would behave in the manner observed, subliming at the temperatures reached during smoking and tending to condense again on cool moist surfaces as represented by the butts. The ab-

sorbent cotton moistened with distilled water caught nearly all the arsenic present in the smoke. This fact is not reassuring when it is called to mind that the tissues of the mouth and lungs are normally moist.

PER CENT OF VOLATILE ARSENIC

Remington's pipe smoking tests indicated that about 50 per cent of the arsenic was volatile. The results of our own investigations, as shown in Table III, indicate maxima of 34.7, 41.3 and 32.8 per cent respectively, for

TABLE III

PERCENTAGES OF ARSENIC VOLATILIZED DURING SMOKING OF CIGARS, CIGARETTES, AND SMOKING TOBACCOS

Averages				5.0	25.6	30.6

* Each test composed of 1 cigar, 4 cigarettes, or 5 grams of smoking tobacco.

the brands of cigars, cigarettes, and pipe tobaccos tested.

These figures were obtained by adding the quantities of arsenic contained in the unpuffed and puffed smoke and the quantity absorbed from the puffed smoke by the butt. This last quantity was ascertained by calculating the amount of arsenic that should be contained in the butts, knowing the weights of the entire cigar or cigarette, the weight of the butts, and the total weight of arsenic present, then subtracting this theoretical weight from that actually found by analysis.

The wide variations in the percentages absorbed by the butts, as shown in Table III, cannot be readily explained. They may be due to differences in moisture content or probably to the degree of packing of the tobaccos. However, the average results for percentages of arsenic absorbed should be reassuring to cigar and cigarette smokers and to pipe smokers who empty their pipes before reaching the "last drag."

SUMMARY

1. An apparatus is described for use in determining volatile arsenic and

other substances evolved during the smoking of cigars, cigarettes, and pipe tobacco.

2. Analyses of popular domestic brands of cigars, cigarettes, and smoking tobaccos show a range from 8.3 to 50.0 p.p.m. of As_2O_3 as compared with a range of 7 to 38.5 p.p.m. found by Remington in domestic smoking and chewing tobaccos.

3. On the basis of average figures, the arsenic inhaled in smoking 1.35 lb. of cigars, 0.57 lb. of cigarettes or 0.16 lb. (2.6 oz.) of pipe tobacco is calculated to be equivalent to that present in 1 lb. of food containing 1.43 p.p.m. of As_2O_3 which is the maximum permitted by law for food products.

4. The proportion of total arsenic volatilized during smoking ranges for cigars from 15.1 to 34.7 per cent, for cigarettes from 32.2 to 41.3 per cent, and for pipe tobaccos from 26.1 to 32.8 per cent. Remington reported about 50 per cent volatile in similar tests on pipe tobaccos.

"Healthmobile" in Maryland

SEVEN counties in southern Maryland and on the eastern shore were visited by the "Healthmobile" of the Bureau of Child Hygiene of the Maryland State Department of Health on its tour this summer. During the eleven weeks of the tour, 85 communities were visited and 89 health conferences were

held for the examination of infants and children under school age. Of 1,589 children examined, 1,137 needed follow-up care of some sort, about 216 were underweight, and 142 had unhealthy tonsils. Of the total number, 1,341 children were given dental examinations and 767 were treated by the dentist.

Responsibility for the Health Program

A DISCUSSION

CHARLES F. WILINSKY, M.D., F.A.P.H.A. (*Life Member*)

*Deputy Commissioner, Child Hygiene Division and Director of Health Units,
Department of Health, Boston, Mass.*

I SUBSCRIBE most heartily to the principle stressed by Dr. Fishbein that the physician should be the key man in matters affecting the health of the people, but I am content that the reason the general practitioner is not occupying this position more frequently is because of laxity and failure on his part rather than because of the fault of health officers or organized groups. The staggering maternal mortality in the United States, the high infant death rate during the first 2 weeks of life, and the high incidence of smallpox mentioned by Dr. Fishbein are but some of the evidences of failure on the part of the family physician to carry on in sufficient measure the practice of preventive medicine and the ideal functions of the family physician.

Dr. Fishbein speaks of the concern the family physician has for and the intimate touch he keeps with the lives of his patients and their families in matters both affecting health and disease. It would seem that a reasonable concern on his part and the exertion of sufficient influence would result in a greater utilization of this service by the laity and a greater participation on his part in the practice of preventive medicine. I know that in Boston we have made effort after effort to develop

and extend the practice of preventive medicine in the office of the general practitioner of medicine. I could offer much documentary proof in support of the energy expended by representatives of health departments in the United States in efforts to inform the layman of the value and significance of certain preventive measures and to encourage them to go to their own family physicians for the obtainment of the same. Unfortunately, the doctor has not been so coöperative and in many instances he has made very little effort to render these services to patients routed there.

I yield readily to the principle that the public health officer should without question refrain from depriving the family physician of the opportunity to render preventive service, and that it would be extremely unintelligent for health officers to set up the premise that it is better to examine children and others in large groups than individually by the family doctor. One can have very little respect for such judgment, yet I am sure that Dr. Fishbein agrees with me that the all important thing for the common good is to see to it that children do get examined, that they get immunized and vaccinated, in short, that everything possible be done for the upbuilding of their physical and mental health.

I sincerely feel that the *complete responsibility* for individual health cannot be delegated at this time entirely to the

* Discussion of paper by Morris Fishbein, M.D., entitled "The Physician and Public Health Officialdom," appearing in December issue of the *Journal*, p. 1223.

family physician. Dr. Fishbein has called our attention to the attitude of the family physician during the so-called golden years of 1928 and 1929, who was likely, when asked to do something in the way of preventive work, to say that his time was occupied fully with the care of the sick. Unfortunately this was not the answer given only in the years 1928 and 1929, but reflects the general reaction of the medical profession during the many years in which preventable diseases have been reduced, the infant mortality rate markedly lowered, the tuberculosis deaths cut almost in three. Any student of medical history must and will acknowledge gladly that the medical profession has of course played a most important part in this improvement. It must be remembered, however, that the ones responsible for this improvement have been the physicians of vision and judgment both in private practice and employed by health departments. Unfortunately the rank and file of the medical profession have lagged perceptibly behind.

I join gladly with Dr. Fishbein in paying well deserved tribute to those members of the medical profession who have done so much for the promotion of the public health, and I agree with him that there can be no question that the physician of the future must be a practitioner of preventive medicine. May I call attention to the fact that in a paper read by me ten years ago, entitled "The General Practitioner and the Practice of Preventive Medicine," I pointed out the advantages to the family physician in engaging in this essential service, as well as emphasized his ability to carry on this work.

I feel as Dr. Fishbein does about the obligation of health departments to carry on and further intelligent health education and subscribe to the theory that it is the job of the wide-awake health officer to get over to the public

certain health needs and values. The intelligent health officer will realize in its broadest sense the importance of enlisting the physicians in his community in the practice of preventive medicine, and he will see to it that the public is informed sufficiently about the relative advantage of going to their own doctors for this type of service. It is important for him to remember that more people will be reached and more preventive work done when more doctors of medicine will participate in this program.

Dr. Fishbein has painted a true picture of the health hazards influenced and increased by modern urban life. These have been in a marked measure the motivating influence for the increase of public health functions.

We have talked so far about the medical profession and public health officers. It would seem pertinent to say a word in consideration of the mass of people who are to be served, the so-called general public. Private practitioners of medicine, hospitals, and dispensaries have served and continue to serve the public in the field of curative medicine. While we must acknowledge the existence of the impostor who will go to a free dispensary or charitable hospital when he can well afford to pay, nevertheless, the income of the medical profession, insufficient though it may be in many instances, must and does come from that portion of the public who express a preference for the services of a private practitioner. It would seem reasonable to believe that the public will exercise the same discrimination and express the same preference in the preventive field. In the long run the public gets about what it wants and, whether we like it or not, the people will make their own choice. Many are going to want preventive service from their own practitioners of medicine when that body of men and women will be ready and willing to give

it to them. Some of the tax payers are going to want public bodies to give them preventive service, as they now get public education, police and fire protection.

I do not fear the bugaboo of state medicine but am rather optimistic about the practitioner of the future, to whom the principles of preventive medicine have been taught as part of his medical training, carrying out in practice the best principles of preventive medicine. The family unit, mindful of the fact that its physician is not only trained but willing to apply prophylactic measures, will come to him for it. On the other hand, there will always be here and there a group of people who will want free service, and another group who will in a measure argue that it is a public function and obligation to give it to them.

I cannot subscribe at this time to the complete abandonment by health officials of such services as prenatal care, well baby and preschool conferences, preventive inoculation clinics, tuberculosis preventive service, etc. It does not seem to me timely to refer all people in need of these prophylactic services to the offices of the private practitioner of medicine. I must prefer to endorse a program which has in mind the education of the community for better health, for the dissemination of advice to people, to seek these services from their own family doctor, and the maintenance of clinics for the indigent as well as for those who are not inclined at this time to accept private service. I cannot help thinking, too, that clinics maintained by health departments are valuable ocular educational demonstrations

of far-reaching beneficial effect, in the long run, to the medical profession. It may be wise to wait a while, watch further efforts like those of Dr. Vaughan in Detroit, and evaluate comparative results, in order to determine whether this or some other plan is the best way by which we may obtain the participation of the medical profession in public health programs.

May I mention Boston again in calling attention to the fact that while approximately 10,000 babies and preschool children out of a preschool population of over 75,000 are brought to the clinics of the health departments, the other 65,000 children are apparently receiving no prophylactic services. It would seem that ethical efforts could be exerted by the family physician, resulting in getting these children to their offices. We in the Health Department are constantly making efforts to get them there. We need the coöperation and willingness of the doctors of the city to obtain the necessary and needed results among this large group of our population—indeed a fertile field for the general practitioner.

It is admitted that the complete responsibility for the health program cannot be delegated to either the medical profession or the health officer. There appear to be both work and glory for both groups and it is the duty of those who speak for organized medicine as well as of those who speak for so-called official public health to harmoniously find the middle of the road, after which both groups should work shoulder to shoulder for common betterment and for the ultimate good of all.

MILK CONTROL AND PUBLIC HEALTH

UNDER the federal agricultural adjustment act, milk marketing agreements have been approved by the Secretary of Agriculture for most of the marketing areas of the country. An exception is the New York metropolitan area for which an agreement, proposed by the industry, now is under consideration [by the U. S. Department of Agriculture]. These marketing agreements, different for each area, provide, in general, prices to be paid to dairy farmers, selling prices to consumers, a production control plan, a code of fair practices, and for some areas a "pooling" of prices to producers whereby each producer gets a uniform price for his product except for butterfat and freight differentials. In each of these agreements the industry obligates itself to conform to all public health requirements governing milk sanitation in the area.

Over-production of milk and a reduced consumption had brought chaos into many milk markets through price cutting and panic prices to dairy farmers. Such conditions were of dubious benefit to the consumer. An uninterrupted supply of safe milk could not long be expected from producers on the verge of bankruptcy. The States of New York, New Jersey, and Connecticut preceded the federal government with state laws to regulate the milk industry essentially as a public utility and primarily for the benefit of dairy farmers.

There is no real surplus of milk production in the country if the nutritional needs of the population are considered instead of the present paralysis of buying power which has reduced by 25 per cent the milk consumption of some areas. Governmental control of milk production and prices is designed primarily as a first aid measure for a (stricken) sick industry. This control will fall short of its potential good to the public unless it is used aggressively to promote the sanitary quality of milk and its increased utilization.

The milk supply of most cities is not yet of a uniformly satisfactory sanitary quality. There are still many tuberculous cattle in dairy herds. The elimination of contagious abortion from herds has scarcely begun. If there are too many cows, eliminate those which are diseased; if there is a "surplus" of milk, exclude that which is unsafe.

Those concerned only with the economic aspect of milk control neglect the public health aspect. Health authorities thus far have had no voice in the milk marketing agreements. Here is an opportunity which yet can be seized to promote the sanitary quality of our most important single article of diet and our most prolific source of food-borne disease.

PUBLIC HEALTH AND THE PRICE OF MILK

THE price of market milk is a matter of great public interest, because pure milk is an indispensable food for all persons at all times. In periods of economic stress, quality milk is of even greater significance to the people, since it must be the basis of emergency nutrition and is the most essential dietary factor in the maintenance of health, especially of the children who are our future citizens.

Economic problems involved in the production and distribution of milk are as significant to the public health as are sanitary problems. Recognizing the fundamental principle that an adequate supply of clean and safe milk must be provided to all families at a reasonable price throughout the year, the federal government and several state governments have recently enacted legislation and created administrative boards to deal with milk control. These boards, upon which the state health departments are usually represented, have come into existence coincidentally with strikes and other disorders in the milk industry and have been endeavoring to stabilize prices and regulate production and distribution for the benefit of all concerned.

The cost of milk, like that of any other commodity, is governed by a number of factors, of which supply and demand is probably the most significant. The dairy industry has grown rapidly and extensively in this country in recent years. Between 1929 and 1933 there was, in fact, an increase of 14 per cent in the number of dairy cattle, or a rise from about 21,000,000 cows to about 24,000,000. In 1932 more than 100 billion pounds of milk were produced, of which 29 per cent was utilized for market milk, somewhat more for butter, and comparatively small percentages for cheese, ice cream, and the manufacture of such concentrated milks as evaporated, powdered, and condensed.

This expanding dairy industry ran full tilt into the depression. Consumption of milk and dairy products, never up to the optimum for the best interests of national health, has decreased. Despite the ardent efforts of physicians, health officers, welfare workers, nutritional authorities, and government officials to induce the public to consume more rather than less milk, there has been a decrease in fluid milk consumption during the last year of at least 5 per cent for the country as a whole, and as much as 15 or 20 per cent in some sections. Because of this greater national production and smaller consumption of milk, tremendous surpluses are now on hand in all parts of the country.

Sanitary measures, including inspection, testing, and laboratory control, have added greatly to the cost of milk, although all progressive dairymen agree with health officials that sanitary measures are not only necessary, but are a good

investment for all concerned. Milk sheds have been established in areas about metropolitan cities, with the result that certain producers have been excluded from these sheds because of failure to comply with requirements such as tuberculin testing, proper methods and conditions of production, and other desirable hygienic procedures. Many agricultural writers are convinced that the supervision of milk sheds has not been entirely free from politics and the baneful influences of political racketeering.

Two other factors have also entered into this complicated situation. One has been the organization of groups of producers into coöperative associations, which have been helpful in raising the quality of milk, although not always successful in keeping up the prices paid to the farmer. The second factor has been the creation of large corporations with national interests as distributors of milk and dairy products.

The large milk company doing a legitimate business offers certain advantages, not only to the farmer but to the public generally. Officials of these companies have always insisted upon, and have achieved rigid sanitary supervision. Because of their size, these companies have been able to pay bonuses to producers for the best milk, and also can provide adequate technical facilities for milk control. These concerns, with branches in many cities and interests in many products, can divert and utilize surpluses to advantage and thus maintain uniform distribution and prevent waste in spite of the tremendous fluctuations in demand due to sudden climatic changes and other exigencies.

One criticism of the big milk companies has been that they have "made too much money." There is much discussion of the apparent spread between the price paid to the farmer for his milk and the price paid by the consumer. Persons unfamiliar with the facts believe that most of this spread, ranging from 5 to about 7 cents, represents only profits to the distributor, not knowing that most of it goes into the necessary costs of sanitation and sanitary supervision, transportation, pasteurization, and delivery. The actual profit accruing to most of the large milk companies in prosperous times is less than three mills (\$0.003) per quart of milk sold and now is often much less than that. The amount that goes into administrative overhead is so small that if it were eliminated, the retail price of milk would be unaffected.

Pure milk is economical at its present prices of from 9 to 12 cents a quart in some sections, and 10 to 15 cents in others, for the best grades of pasteurized milk, and it would be economical as a food if the cost were even greater, though there is little likelihood of any considerable increase under prevailing conditions. Milk, appropriately known as our "most nearly perfect food," is nutritionally superior to any other single food and to many combinations of foods. There is no substitute for milk in the diet and there is no better return on the investment when at least one-fourth of the average family food budget is spent for milk and dairy products.

Health officials can contribute to the solution of the problems of the dairy industry, which are also directly the problems of public health, in enforcing at all times reasonable sanitary regulations for the production and distribution of milk, and by promoting a greater consumption of pure milk, either certified or pasteurized. Regulations should be uniform on a state-wide basis and should be shorn of unessentials. What is worth enforcing should be enforced, but in a rational manner, and with no tendency to lower the standards of quality milk in order to provide a cheap milk.

Public health will be improved whenever milk consumption is increased. The maxim of a quart of pure milk a day in some form for every growing child, for every nursing and expectant mother, and for every malnourished person, and at least a pint for every normal adult has a sound scientific basis. The health officer can perform no more important function than impressing these facts upon his constituents. It is his duty to take effective measures to guarantee clean and safe milk for the people and then see to it that they appreciate its acknowledged benefits in the field of human nutrition.

THE ASSOCIATION AND ITS SECTIONS

A FELLOW of the Association has asked what the parent body should expect of its sections, and what the sections should expect of the Association. An inquiry was sent out to the various section officers requesting replies to these two questions. The answers were somewhat discursive, but agreed on several points.

While a section should be well organized within itself, it should remember that it is one of the integral parts of the Association as a whole. Support of the parent body is its first duty. In performing this rôle it should be zealous in securing Association membership by adding to the number of its section members; it should prepare its own program for the Annual Meeting, having in mind not only the interest of the section itself but the educational contribution it can make to the entire Association along its lines of special interest; in its current activities it should consider primarily the development, standardization, and evaluation of procedures in its own field; but in this process it should continually study the interrelations of its own special work with that of the whole Association; on its own initiative or when requested, it should enter freely into collaboration with other sections in matters of mutual interest.

Finally, there is another activity which each section should take under serious and sympathetic consideration. This is the material support of the Association itself. Fixed revenue is painfully limited. Productive avenues of research and promotion stretch in many directions, but are fenced off by this limitation. Each section should feel a sense of responsibility for building up the resources of the Association through gifts and bequests from its own members or wealthy and influential friends whenever the occasion presents.

Turn now to the question as to what the sections have a right to expect from the Association. First they may expect and demand economical and efficient administration of the affairs of the Association. This is assured by an experienced staff at the central office who work devotedly for the welfare and strengthening of the organization on what are considered very slender salaries for the type of service required. But a still stronger assurance is guaranteed by the hours of devoted service to the affairs of the Association given from their crowded lives and with no remuneration by the officers and members of the Executive Board. If members of sections could appreciate what this involves in the way of individual sacrifice for the good of the Association it would serve as a powerful inspiration to their deeper interest in the society's progress.

Specifically the services which the organization can render its sections can be divided into those of general administration and those afforded by the five standing committees of the Association—Meetings and Publications, Fellowship

and Membership, Administrative Practice, Research and Standards, and Professional Education. General administration supplies the quarters, equipment, and business structure essential to practical operation. It aids in the proper assignment of activities and in the correlation of processes and results. Every effort is made to hold its cost within the minimum limit compatible with efficiency. The first two Association committees are primarily administrative, the one performing the vital functions of conducting the Annual Meeting and producing the *Journal* and other publications, the other an equally essential service in developing Fellowship and membership. Their activities are indispensable to the survival of the Association.

The three other committees are charged with the promotion of approved methods of public health administration, the study of existing practices, field service to health departments, research, the establishment of scientific standards of public health methods and procedure, and the promotion of adequate professional education. While the administrative functions of the central office act more or less automatically in their service to the whole Association, the scientific committees are equipped to render specific service to the various sections along the lines of their several activities.

In general, the sections may expect of the parent body:

1. Helpful coöperation, through its Standing Committees, in any matter in which the section requires assistance or collaboration from any other subdivision of the Association.
2. Sympathetic consideration of any appeal from a section for publicity or propaganda which it may require in connection with its policies or practices.
3. Allocation of funds in reasonable amount for specified activities which it desires to undertake, and for traveling expenses of its officers and committee members when special meetings are necessitated.
4. Provision of clerical and mechanical service to section committees when such service cannot conveniently be provided by the committees themselves.
5. Provision of opportunities for social and professional assembly at the Annual Meeting, consistent with the funds available.

Vastly more service could be rendered by the Association were more funds available. Every new membership or Fellowship secured by the sections has a double significance. It strengthens the Association but, of far more importance, it sets free just so much potential energy to be transformed into dynamic assistance to the sections by putting added resources at their disposal. The sections can serve their own interests in no way better than by putting forth their efforts to double their membership during the year 1934.

ASSOCIATION NEWS

S O S

AN OPPORTUNITY FOR YOU

THERE are 473 of our members and Fellows who have been unable to pay their 1933 A.P.H.A. dues. The rules and regulations necessitate these individuals being dropped from the Association unless dues are paid by them or by their friends. The number of these members and Fellows in each section is given below:

Health Officers Section.....	126
Laboratory Section.....	43
Vital Statistics Section.....	6
Public Health Engineering Section....	33
Food and Nutrition Section.....	22
Industrial Hygiene Section.....	16
Child Hygiene Section.....	40
Public Health Education Section.....	46
Public Health Nursing Section.....	68
Epidemiology Section.....	5
Unaffiliated	68

It has been suggested that the members and Fellows now having an income from positions which they continue to hold, come to the rescue of these less

fortunate colleagues, through the assumption of responsibility for such unpaid dues. This matter can be handled privately, without causing the slightest embarrassment to the member or Fellow who is now in arrears. Just send \$5.00 or \$10.00 to the Secretary of the Committee on Fellowship and Membership. Your contribution will then be used to cover the dues of a member or Fellow of your Section.

The responses to this suggestion, made first at the Indianapolis Annual Meeting, lead us to believe that the plan will be heartily welcomed by the membership.

Help save our members and Fellows from the embarrassment of losing their standing in their professional society, and help the Association. This is an S O S call to the loyal members of the Association, and has the approval of the Governing Council.

SUMMARY OF EXECUTIVE BOARD AND GOVERNING COUNCIL TRANSACTIONS AT INDIANAPOLIS

THE following summary of the more important actions taken by the Executive Board and the Governing Council in their official sessions at Indianapolis during the Annual Meeting are printed here for the information of the membership.

1. A committee was authorized to confer with the National Committee on Mental Hygiene, the American Psychiatric Association, and the American Neurological Association on the advantages or disadvantages of creating a Section on Mental Hygiene in the American Public Health Association.

2. The Executive Secretary was authorized to provide a place on the agenda of the first meeting of the Governing Council at the time

of the Annual Meeting for the presentation of questions and comments on Association policies by members of the Association.

3. Prof. C.-E. A. Winslow was reappointed chairman of the Committee on Administrative Practice.

4. Dr. C. C. Young was reappointed Chairman of the Committee on Meetings and Publications.

5. It was agreed to continue to agitate the matter of increasing the Endowment Fund and to make available to a list of influential people reprints of the Presidential Address of Dr. John A. Ferrell, including a form of bequest.

6. The plan of the Committee on Fellowship and Membership to retain unpaid members by appealing to members in good standing to assume responsibility for the dues of

at least one member in their section was approved. Already several of our members have taken this opportunity to assist some of their fellow members.

7. Sixty-two individuals were elected to Fellowship and 12 to Life Membership.

8. Reports of the four Association Committees, Committee on American Museum of Hygiene, Committee on Stabilization of Health Appropriations, Committee to Safeguard Public Health Consistent with Sound Government Economy, and Committee on Autopsies, were approved and will appear in the *Year Book*.

9. Resolutions on the following subjects were adopted. They will be printed in the *Year Book*.

Resolution of Appreciation to Dr. John A. Amyot

Resolution of Appreciation to the Local Committee

Resolution in Memoriam

American Legion Resolution

Revision of Food and Drugs Act

Federal Relief Administration Policy

United States Public Health Service

10. Pasadena was selected as the next Annual Meeting City.

11. Mr. H. A. Whittaker and Miss Katharine Tucker were elected to the Governing Council to fill unexpired terms.

12. An "Official Declaration of Attitude of the American Public Health Association on Desirable Standard Minimum Functions and Suitable Organization of Health Activities" was adopted. It will be published in full in the *Year Book*.

SECTION RESOLUTIONS

ADOPTED AT THE INDIANAPOLIS ANNUAL MEETING

Laboratory Section

DEATH OF DR. LEON C. HAVENS

WHEREAS, the Laboratory Section of the American Public Health Association has lost one of its most active members through the untimely death of Dr. Leon C. Havens, and

WHEREAS, the contributions of Dr. Havens to the advancement of public health laboratory procedures are outstanding, be it

RESOLVED, that the Laboratory Section express deep conviction that in the death of Dr. Havens, the Laboratory Section, as well as the whole Association, has suffered a great loss, and be it

RESOLVED, that this resolution be recorded in the minutes of the Section and that a copy be sent to his bereaved family.

keenly aware of the services rendered by Mr. Wachter during many years of devotion to the section's affairs, his dependability, his faithful attendance at meetings, his keen discussion of scientific matters with which he was concerned, and his work as a member of the Committee on Standard Methods from 1924 to the time of his death; be it

RESOLVED, that the Laboratory Section express its deep conviction that in the death of Mr. Wachter the Laboratory Section, as well as the whole Association, has suffered a great loss, and be it

RESOLVED, that this Resolution be recorded in the minutes of the Section and that a copy be sent to his bereaved family.

DEATH OF MR. LEONARD M. WACHTER

WHEREAS, the Laboratory Section of the American Public Health Association has lost a valued and active member through the death of Mr. Leonard M. Wachter, and

WHEREAS, the Laboratory Section is

DEATH OF PROFESSOR FREDERIC P. GORHAM

WHEREAS, the Laboratory Section of the American Public Health Association has lost through the death of Professor Frederic P. Gorham one of the pioneers in public health laboratory procedure, and

WHEREAS, the Section is keenly aware of its debt to Professor Gorham not only because of his own outstanding contributions but also because of his rare qualities of leadership and his ability as a teacher—his inspiration brought into the Section and into the Association some of its most useful members; he served as Section Chairman in 1912–1913, and subsequently was almost constantly a member of important committees—therefore, be it

RESOLVED, that while the Laboratory Section can no longer have the charm of Professor Gorham's actual presence, we feel that he has an immortality among us through "his boys" in public health work, and be it

RESOLVED, that this Resolution be recorded in the minutes of the Section and that a copy be sent to his bereaved family.

DEATH OF CLARENCE A. SHORE

WHEREAS, the Laboratory Section of the American Public Health Association has suffered an irreparable loss through the death of Dr. Clarence A. Shore, and

WHEREAS, the Laboratory Section is keenly aware of the faithful and dependable services of Dr. Shore, through his constant attendance at meetings, as Section Chairman in 1930 and 1931, and through his contributions to public health and laboratory procedures; be it

RESOLVED, that the Laboratory Section express deep conviction that in the death of Dr. Shore, the Laboratory Section, as well as the whole Association, has suffered a great loss, and be it

RESOLVED, that this resolution be recorded in the minutes of the Section and that a copy be sent to his bereaved family.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

Harry C. Hummell, M.D., Health Bureau, 82 Chestnut St., Rochester, N. Y., Deputy Health Officer

Laboratory Section

Mildred A. Engelbrecht, M.S., 311 Agricultural Hall, Univ. of Wis., Madison, Wis., Instructor in Agricultural Bacteriology
Professor Alexander Klein, M.D., Dept. of Hygiene and Bacteriology, University of Groningen, Groningen, Holland (Associate)
Mary McCrath, c/o Ferris, 35 E. 17 St., Brooklyn, N. Y., Bacteriologist, Dept. of Health
Fred S. Paine, B.A., M.S., P. O. Box 916, Hilo, Hawaii, Bacteriologist, Bureau of Health
Lawrence Sophian, A.B., M.D., 428 West 59 St., New York, N. Y., (Associate)
Oscar Von Lange, Soledad, Calif., Dairy Technician

Vital Statistics Section

Elizabeth L. Brezee, A.B., 5126 Waterman Ave., St. Louis, Mo., Vital Statistician, St. Louis Department of Health

Public Health Engineering Section

DeWitt S. Abell, M.S., 321 Salisbury Rd., Statesville, N. C., Assistant Engineer, State Board of Health

Public Health Education Section

Harriet M. Gale, R.N., B.A., Grinnell College, Grinnell, Ia., Instructor of Hygiene
Grace D. Lucas, Jordan No. 193, Ann Arbor, Mich., Student (Associate)
Hubert O. Swartout, M.D., D.N.B., M.S., Box 2772, New Haven, Conn., Post graduate study, candidate for degree of Dr.P.H. at Yale University
Adele von Gruening, 919 N. 5th St., Sheboygan, Wis., County Nurse

Public Health Nursing Section

- Rosamond S. Hammer, A.B., 119 Elm. St., Branford, Conn., Chairman, Nurses Committee, Branford Visiting Nurse Association
- Ann M. Hellner, B.A., B.E., Saginaw General Hospital, Saginaw, Mich., Director, Visiting Nurse Association
- Hattie Hemschmeyer, R.N., 415 Central Park West, New York, N. Y., Executive Secretary, Lobenstine Midwifery Clinic, Inc., and of the Association for the Promotion and Standardization of Midwifery, Inc.
- Anna C. Potter, R.N., 1045 N. 5th Ave., Tucson, Ariz., Pima County Public Health Nurse

Epidemiology Section

- Harold D. Choate, M.D., M.P.H., A.B., Rm. 25, Municipal Courts Bldg., St. Louis, Mo., City Epidemiologist
- James W. Loughlin, M.D., Newcastle, Me., District Health Officer
- George E. Riley, M.D., C.P.H., B.S., State Board of Health, Jackson, Miss., Malaria-ologist, Bureau of Communicable Diseases

Unaffiliated

- William J. Fordrune, A.M., LL.B., M.D., Hunter College, Park Ave. & 68 St., New York, N. Y., Professor and Head of Dept. of Physiology and Hygiene.

APPLICANTS FOR FELLOWSHIP

Health Officers Section

- Taswell P. Haney, Jr., M.D., C.P.H., McComb, Miss.
- Thomas H. Johnston, M.D., Dr.P.H., West Branch, Mich.
- Clifford E. Waller, M.D., Washington, D. C.

Laboratory Section

- Walter A. Jamieson, A.B., Indianapolis, Ind.
- William Litterer, A.M., Ph.C., M.D., Nashville, Tenn.
- Charles G. Merrell, S.B., Cincinnati, Ohio
- Edward J. Pugh, B.S., Forty-Fort, Pa.
- Elliot S. A. Robinson, M.D., Ph.D., Boston, Mass.

Vital Statistics Section

- Elizabeth C. Tandy, D.Sc., Ph.B., Washington, D. C.
- William C. Welling, B.A., Hartford, Conn.
- Emma A. Winslow, Ph.D., M.A., Washington, D. C.

Public Health Engineering Section

- Lewis Shere, B.S., Chicago, Ill.

Food and Nutrition Section

- Laurence P. Geer, S.B., Cambridge, Mass.
- Julian H. Toulouse, B.S., Ph.D., Washington, D. C.

Public Health Education Section

- Cara L. Harris, B.S., Knoxville, Tenn.
- Burt R. Rickards, B.S., Albany, N. Y.

Epidemiology Section

- Carl C. Dauer, M.D., M.P.H., New Orleans, La.

Unaffiliated

- Everett S. Elwood, Ph.B., Philadelphia, Pa.
- Clarence A. Horn, M.A., Reading, Pa.
- Elnora E. Thomson, R.N., Portland, Ore.

PUBLIC HEALTH ADMINISTRATION

Amebic Dysentery in Chicago—On November 27 the Health Commissioner of Chicago reports that up to that date 348 cases of amebic dysentery have been reported in connection with the Chicago outbreak. The outbreak, which apparently made its appearance in August, has centered around certain hotels where it is reported that food handlers have been found either to be suffering from dysentery or are carriers. It is through this channel that visitors to Chicago have been exposed and there are now 112 cities involved in the outbreak. In addition to the 348 cases there have been reported 298 carriers and 24 deaths. The infection has been traced to almost every state, as well as to Canada and several foreign countries. The Chicago Health Department reports that "almost daily, we learn of cases of amebic dysentery that are diagnosed as appendicitis or ulcerative colitis and are undergoing operation. Unfortunately, when this occurs, the outcome is usually fatal. The correct diagnosis in many of these cases is made only after autopsy. Many cases of amebic dysentery are being treated as intestinal influenza, mucous colitis, appendicitis, or ulcerative colitis."

Because of the association of food handlers with the outbreak, the Health Department in Chicago has been enforcing very stringent regulations with regard to the sanitation of public eating places. Particular emphasis is placed upon the need of handwashing facilities for kitchen employees. In some hotels the employment of monitors is required, it being their obligation to see that after each chance contamination the food handler washes his

hands thoroughly with hot water and soap and that individual towels are used. Employees are also required to dip their hands in a chlorine solution and make use of a handbrush in removing unusual accumulations of dirt.

The regulations of the Chicago Health Department require that where food handlers are found to harbor the cysts of *ameba histolytica*, they should not be permitted to continue their usual occupation until adequate treatment and examinations have been completed. Carriers are treated either at home or at a hospital under conditions approved by the Health Department. Carriers who are non-food handlers are permitted to continue their usual occupation.—Herman N. Bundesen, *J.A.M.A.*, 101:1636 (Nov. 18), 1933, and special releases of the Department of Health.

Idleness and Health—A study is undertaken to answer two questions which are being asked on every side: Do families with most idleness show most sickness? Does employment status affect the nature or severity of illness reported? A careful analysis of the district chosen precedes the study. Nationality, type of occupation ordinarily pursued, age groups, housing, and sources of income were considered. Comparison is made between health conditions found in November, 1930, and April, 1932. It was shown that only 15 per cent of those included in the study as employable were working at the same job for the intervening period of 1½ years. In April, 1932, 38.7 per cent of the families contained sick persons as against 24.1 per cent in November, 1930.

There is much evidence that there

found sick in 1932 were receiving less medical attention than those found in the 1930 survey. Malnutrition heads the list in the prevalence of selected diseases in both surveys. Using the rate of bed patients per 1,000 persons in April, 1922, as 100, the corresponding rate for November, 1930, becomes 89.1 and for April, 1932, it is 128.3. The author presents factors which might have a distinct bearing upon the interpretation of the findings of the study, but with this consideration she concludes that "sickness is most frequently found in homes of idle persons who are normally at work."

Carefully prepared charts and tables make the study easy of comprehension. It is a distinct contribution to a subject which is causing great concern.—Gwendolyn Hughes Berry, Ph.D. *Idleness and the Health of the Neighborhood. A social study of the Mulberry District. Issued by the New York Association for Improving the Condition of the Poor.*

Zero Diphtheria Death Record in Bellevue-Yorkville for 1933—With not a single death from diphtheria during the period March 7, 1932, through November 28, 1933, in its area, the Bellevue-Yorkville District has surpassed its September 1, 1929, to February 28, 1931, low record in that respect. For the first 10 months of this year, there have been 71 deaths from diphtheria in the entire city, a new low record, with 16 in Manhattan and none in the Bellevue-Yorkville District since March 7, 1932, and through November 28 of this year. In the 10-month period of this year, there were 1,624 cases of diphtheria in the city, 545 in Manhattan and 53 in the Bellevue-Yorkville area.

For the first 10 months of 1933 the diphtheria case rate was 46 per 100,000 population in the Bellevue-Yorkville District, as compared with a case rate

of 252 per 100,000 population in 1928. In 1932 the case rate in this area was 58 per 100,000.

The success of anti-diphtheria work in Bellevue-Yorkville is shown by the fact that in 1928, the year before the Demonstration began its intensive anti-diphtheria campaign, there were 405 cases of diphtheria and 28 deaths from that cause. In 1929 the number of cases dropped to a total of 267 and the deaths to 9, while in 1930 the cases fell to 94 and the deaths to zero. The latter record stood until March, 1931, when diphtheria began to show a slight increase. In 1932 diphtheria cases in the area decreased to 83 and there were 3 deaths in January and February.

As compared with Manhattan and New York City, the records show that while Bellevue-Yorkville had a case rate decrease of 77 per cent during the period 1928–1932, Manhattan registered a decrease of 74 and New York City 69 per cent. The reduction of the death rate from diphtheria for the same period in Bellevue-Yorkville was 88 per cent, in Manhattan 80 per cent, and in New York City 70 per cent.

Southern Berkshire District, Mass.—The purpose and results of the public health developments of the past 2½ years in the Southern Berkshire District of Massachusetts, as outlined in a recent report, indicate the value of coöperative health work. This is a joint enterprise of a group of towns, the State Department of Health, and the Commonwealth Fund. "The State Commissioner of Health had for some years believed that if towns worked together, their citizens could secure as much protection against epidemics and as good health service generally as larger towns and cities already enjoyed." In 1931, a joint Committee of the Southern Berkshire Health District was formed by the boards of health of 16 towns, and this committee appointed

a medical director with authority to act as the agent of each board.

One of the first activities of the medical director was to persuade the boards of health which he represented to make uniform their regulations for quarantine and other communicable disease control. He also became a diagnostic consultant to physicians. The third step was to send a public health nurse, as a regular routine, to every home where a communicable disease occurred, to help the family guard against disease spread. Immunization against diphtheria was stimulated.

To aid in tuberculosis case finding, the health district arranged with authorities to bring a specialist from a state sanatorium to Great Barrington (the headquarters) once a month to examine persons—especially contacts—when the family physician wished assistance. Milk supervision has been coördinated, school nursing services have been strengthened, and in 13 towns, public health nursing is planned and administered as a unit.

In 1932, over one-third of the expectant mothers of the entire district were visited by nurses. A dental hygienist employed by the unit examined the teeth of children in all public schools twice a year, while a local dentist did the necessary fillings or extractions for children, in towns without dentists, at the expense of the town or of the parents. In 11 towns, "well-child conferences" are in operation.

Another contribution of the unit has been to bring leading specialists from Boston and elsewhere to lecture before the physicians of the district on subjects of particular importance to all general practitioners.

St. Marylebone, England—According to the interesting report for 1932, this borough of 1,427 acres with a population of 96,430, has 17,200 inhabited houses with 27,352 families. A birth

rate of 10.97, a death rate of 12.4 and an infant mortality rate of 87 are noted. A feature of the report is a series of tables showing the distribution and characteristics of the population in greater detail than is customary in American reports, but of much value to the administrator.

The main source of the notification of births was the hospitals, 83.6 per cent, with 11.9 per cent from midwives and 3.6 per cent from doctors. Failures to notify the department within 36 hours of birth, as required by law, were said to be comparatively few. The maternity and child welfare program is carried on by official and voluntary organizations, "the connecting link being the Public Health Department of the Council." Two hospitals provide lying-in accommodations, arrange for attention to be given to out-door patients, and conduct antenatal and infant consultations. There are 8 infant and child welfare centers and 4 antenatal clinics available. There is also a dental clinic for mothers and young children open 4 days a week.

Los Angeles County, Calif.—In the 1932-1933 annual report of the county health department laboratory, appear certain interesting deductions: there were 6,465 bacteriological tests made during the year per person, with 132 tests per 1,000 population. The gross salary cost per test was \$.29. The per capita salary cost for the bacteriological division, including chemists, was \$.05. This low cost is partly explained by salary reductions due to the depression and partly by decreased personnel. The total tests for the year of the county bureau of laboratories numbered 122,392.

A central laboratory supplies the 10 district laboratories with stains, reagents, special cultures, media, and assistance during heavy test periods. Fifteen bacteriologists in the division

hold state certificates indicating proficiency in various lines of laboratory work. Talks of both a popular and technical nature for various groups in the county have been frequently given upon request. These are sometimes followed by visits of the groups to the laboratory, or are accompanied by exhibits. These services, coupled with other public relations activities, are effectively described.

It is appropriate to note that this laboratory has developed practical designs of interest to directors, including structural incubator changes, a modification of the Quevenne lactometer, and a Stone Bacteria Colony Counter (described by Bausch & Lomb). Practical research work is undertaken along with routine activities as opportunity permits.

Minnesota.—The annual report of the Public Health Nursing Services in Minnesota under the Department of Health, and exclusive of the twin cities, is presented in graphic form with brief descriptive text. The scope of services rendered in 1932-1933 is compared with *Appraisal Form* standards of the American Public Health Association and with the records for 2 previous years. Besides this interesting information, there are included, all in 20 pages, Suggested Goals in School Health Work, and a directory of 27 advisory committees showing for each the county, the

board chairman, the number of members, and the sub-committees.

One striking result is the increase in visits made by nurses employed in counties and school services. The past 2 years of economic stress called for increased efforts by public health nurses to meet the demands of the communities in their struggles against malnutrition, communicable diseases, and social problems. Of 129,826 visits, 41 per cent were in behalf of school children, 19 per cent for communicable disease, and 19 per cent for non-communicable disease including orthopedic conditions, while the remainder were for adult supervision (7 per cent), maternity and new-born (5 per cent), infant and preschool hygiene (11 per cent). School nurses represent the largest proportion of specialized personnel; furthermore, county nursing services have been influenced by the facilities the school offers in reaching the population in large groups.

In connection with the school work, local doctors and dentists carried a good share of the responsibilities of the annual health examinations or inspections. Volunteer committees, arranged with medical groups for immunizations, vaccinations, skin tests and clinics. Wherever the doctors or dentists made examinations, plans were arranged by the local medical and dental groups with the school board, the nursing committee and the nurse.

LABORATORY

A RAPID AND ACCURATE SEMI-AUTOMATIC DELIVERY PIPETTE

M. W. JENNISON, PH.D.

*Department of Biology and Public Health, Massachusetts Institute of
Technology, Cambridge, Mass.*

THE bacteriologist often has need of an accurate but rapid method for making dilution blanks, measuring exact quantities of broth, agar, etc. The apparatus* described here was designed for such purposes, and may be adapted to various problems.

The apparatus (Figure I) is essentially a double form of the so-called "automatic overflow pipette," the fluid to be distributed being siphoned from a reservoir above the pipette. With each half turn of the stopcock, one pipette fills while the other is emptying. By making the bores of the stopcock and connecting tubes large, filling and emptying is accomplished in 2 or 3 seconds, allowing the operator to fill perhaps a thousand tubes an hour. Speed is not sacrificed to accuracy, since the precision of delivery is ± 0.1 ml. The larger bore also simplifies cleaning.

The particular pipette illustrated here was made to deliver 9.2 ml., so that after sterilization the tubes contain 9.0 ml. The apparatus may, of course, be made and calibrated to deliver any volume desired. Furthermore, in order that this pipette might be sterilized—to measure out sterile media—it was constructed of Pyrex glass and annealed. Such construction makes for a much less fragile piece of

FIGURE I

glassware, even if its sterilization is not contemplated. For delivery of sterile media, a glass or metal¹ bell-shaped cap is placed on the delivery tip.

STANDARDS

ANNA W. WILLIAMS, M.D., F.A.P.H.A.

Bureau of Laboratories, New York City Health Department, New York, N. Y.

IF a single word were chosen to describe one of the most important interests of the Laboratory Section of the American Public Health Association, that word might be *Standards*.

From the beginning of its organization this section has encouraged study, criticism, testing, and helping to establish laboratory standards of public health measures; then it has advised the re-study, re-criticism, re-testing, modifications—destruction even, if deemed necessary—of the accepted standards; and has recommended the altered or new ones to the Association, later through its general Committee on Research and Standards.

We have always recognized the danger of accepting standards as final—of sitting back in our chairs and allowing our laboratory work to be run without comment, according to routine cut-and-dried standard methods even of those that seem most firmly established. We realize that while standards are necessary for good comparative work, there must be “continuous reconstruction” of methods in accordance with growing knowledge; and that this means concerted effort to oversee and evaluate the laboratory work being done throughout the world.

In his talk on “Activities and Trends in the Laboratory Field” at the “Ten Star Final” session of our Washington annual meeting, Dr. McCoy’s subtle observations concerning the widespread view of the instability of standards may well be remembered. He said, among

other things, “just now seems to be a time of more than ordinary questioning of all views and of what were thought to be well established facts.” Again, he said, “One of the outstanding facts that has impressed me in recent years has been the rich harvest to be garnered from the re-working of old fields.”

As we glance over the reports published by members of this section during the past year we are impressed by the fact that several methods in laboratory procedure along both medical and sanitary lines have been criticised, some new ones have been advised, and a few have been considered outworn. For example: Criticisms have been made and changes have been suggested in the methods of milk examination, including examination for milk-borne diseases; in the methods of the disinfection of foodstuffs and eating utensils; in the methods of the examination of various waters, including swimming pools; in the methods of the preparation and dosage of toxoid, of typhoid vaccine, of rabies vaccine, of BCG vaccine; in the methods of preparing and tests for potency of meningococcus serum and hemolytic streptococcus serum. The big problem of the present value of cultures in the diagnosis of diphtheria has been discussed and evidence has been presented in favor of the discontinuance of the method because no longer necessary in the face of the proved worth of diphtheria vaccination and the practicability of its application.

The new methods recommended for consideration are taken up in our Standard Methods report.

The question has been under consideration as to whether our section is

* Presented to the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

handling in the best manner possible all the investigations concerning laboratory standards in public health. Is our Committee on Standard Methods organized in such a way as to receive full value from advancing knowledge, to be able to report reasonably quickly and authoritatively on recommended changes, and to be constantly on the alert for worth while ideas?

Some have thought the present committee too large, others have thought it not large enough to handle all phases of laboratory methods, and several other criticisms have been made—hence a reorganization is being considered.

There is no question but that our Standard Methods committee has done very efficient work in the past, and there is no question in the minds of the majority but that such a committee—in modified form, perhaps—should be continued. The claim that the general Committee on Research and Standards is taking over the work of our committee is based on a mistaken idea of the duties of our committee and of the general committee, as well as of the organization of the Association as a whole.

From the standpoint of organization the functions of a general Committee on Research and Standards must necessarily be: first, general oversight and final approval of investigations on standards carried on by each and every section; second, the development of research involving more than one section; and third, the carrying out of executive measures common to more than one section.

Such a general committee is particularly necessary where there is overlapping of interests as there so often is between many of the sections. We all are aware of the close relationship between the work of the Laboratory Section and that of the Epidemiology, Public Health Engineering, Health Officers, Industrial Hygiene, Food and

Nutrition, and Child Hygiene Sections. The question of undue overlapping—of duplication of work—makes coöperation imperative. It would seem to be peculiarly the function of the general Committee on Research and Standards to organize investigations that involve intimately more than one section, such as the investigations this committee has just planned concerning the most efficient methods of making and administering typhoid vaccine. These investigations belong obviously to the Epidemiology and Health Officers Sections as well as to the Laboratory Section; and so it might logically be engineered—as it is—by the general committee, dividing up the work among these three sections and appropriate sub-committees of the general committee.

There are enough complex investigations in public health that should be undertaken to keep all sections and general committees busy without taking away from any section the work that legitimately belongs to it.

It goes without the need for emphasis that in all public health work involving laboratory problems in standardization, the Laboratory Section should be and wishes to be active in doing its part to help establish laboratory standards in both medicine and sanitation. These activities are so closely related that their separation is more or less artificial and a matter of convenience. Take for example the problem of swimming pool purification. This includes the types, construction, and cross-connections of the pools, the different dangerous disease germs these waters may contain, and the effect of disinfectants on the germs and on the swimmers. You realize at a glance how wide are the relationships.

If any section has not been as active as usual during the past four years in carrying on research and helping to establish standards in public health

work, at least a partial explanation may be given by quoting a line from this year's general report of the Executive Board to the Governing Council, "The necessity for economy has forced the Association to limit its activities to practically the bare essentials of existence."

No committee was able to meet sufficiently often—most of them not more than once in the year. At present, therefore, our criticisms of activities

must be tempered with the knowledge of these adverse times. The investigations of most problems require extra funds which are not included in our diminishing budgets, hence most of us are under the necessity of continuing to look forward into the future for the carrying out of some of our plans. Many plans, however, we are attempting to carry on, and we can report progress and hope for a reasonably speedy fulfillment of them.

VITAL STATISTICS

Vital Statistics for Montreal, Canada, 1922–1932—Analysis of the statistics for the city of Montreal, revised on the basis of the recent census, brings to light some interesting facts concerning vital statistics for the period 1922–1932.

In accordance with the general trend in Canada, the marriage rate in Montreal declined, in 1932, to 6.93 (per 1,000 population) from the figure of 7.57 recorded in the previous year. Comparison of the 1932 marriage rate with that registered in 1922 (8.77), shows a much greater reduction. As an outgrowth of the marriage trend, the birth rate in Montreal also has dropped; in 1932, 1931, and 1922, birth rates of 24.01, 26.59, and 32.50 (per 1,000 population) respectively, were recorded. The period 1922–1932 saw a 26 per cent decline in natality—an even larger decrease than in the marriage rate.

The fall in the proportions of births and marriages is counterbalanced somewhat, however, by the decline in infant mortality to 98.9 deaths (per 1,000 live births) in 1932—a rate much more favorable than that (159.4) shown in 1922. Comparison of the two figures reveals a 38 per cent drop in

the period 1922–1932. Examination of available data also shows that the 1932 infant death rate in Montreal (98.9) is in about the same range as the corresponding figure for the Province of Quebec (94.2). Yet, when the 1932 infant mortality (73.2) for the entire registration area of Canada is brought into the picture, the rate for the City of Montreal does not appear so gratifying.

In 1932, the City of Montreal experienced a general mortality of 11.68 (per 1,000 population)—a rate only slightly lower than that recorded in 1931 (12.08), but 25 per cent lower than the figure of 15.60 registered in 1922. It is interesting to note that the declines in the general death rate (25 per cent) and in the birth rate (26 per cent) were about equal during the period 1922–1932.

Further analysis of the mortality data for the years 1922 and 1932 shows increases in the death rates from cancer (29 per cent); Bright's disease (19 per cent); and organic heart diseases (32 per cent). In contrast, however, the death rate from pneumonia (all forms), declined 44 per cent during the period 1922 to 1932.

Tuberculosis (all forms) also declined 32 per cent in its mortality in the same period. This cause resulted in 100 deaths (per 100,000 population), in Montreal in 1932; in the same year the Province of Quebec registered a corresponding rate of 103. However, as in the case of infant mortality, the tuberculosis death rate in the City of Montreal appears quite high when contrasted with the death rate of 68 from tuberculosis in the registration area of Canada.—*Report of the Dept. of Health, Montreal, P. Q., Canada. Preliminary Report Vital Statistics of Canada.*

Dangers of Early Infancy—The infant death rate has declined enormously during the last decade in Illinois but there has been no improvement whatever in the chance of survival for the baby who fails to live out the first day of life. The threshold of earthly existence is equally as dangerous as ever and the fatal risks of the first day are greater in magnitude than those of any subsequent day on earth for human creatures in general.

Mortality of infants during the first day of life is four times greater than during the second and eight times greater than during the third day of life. In other words, the baby who lives through the first 24 hours has increased fourfold his chances of survival while the one who lives for 48 hours has an eightfold better chance of surviving to adulthood than at the moment of birth.

These interesting facts are revealed by an analysis of infant mortality statistics of Illinois for the 15 years ended with 1932. For babies under 1 day old the losses in 1918 were 16.4 per 1,000 live births reported and in 1932 the rate was 15.5. During the intervening years the rate fluctuated between the narrow margin of 14.8 and 16.4. This is the only age group of infants that experienced no improve-

ment whatever with respect to survival.

For babies included in the 1- to 7-day age group the losses in 1932 were nearly one-third less, in proportion to births, than they were in 1918. Even so, the rate of improvement was much less than for older infants. The death rate per 1,000 births for the 1- to 7-day old group fell from 15.6 in 1918 to 10.6 in 1932 and the decline in rate was constant during the period.

The death rate in 1932 for infants in the 1-week to 2-months age group was just about one-half what it was in 1918. The decline was from 21.1 to 10.6 deaths per 1,000 live births reported. Here again the decline was steadily downward year by year.

Even more striking has been the improvement among older infants. Losses in 1932 among babies between 2 and 12 months old were only one-third of those in 1918. The death rate in this group fell from 48.7 to 16.0 per 1,000 births.

These records indicate that the improvement in infant care has been remarkably effective in saving life after the first few days but that nothing has been accomplished in making safer the first day of life on earth. This fact suggests that prenatal influences dominate the chances of survival of babies during the first 24 hours, while things that can be done for the baby itself become more and more important with each hour of life.

The infant hygiene measures which have been applied with such striking success relate chiefly to diet and feeding on the one hand and to the sanitation of milk supplies on the other hand. Manifestly these measures can do practically nothing for the infant under 24 hours of age. Something more fundamental and something that reaches back into the prenatal existence of babies must be done in order to cut down the losses on the natal day of existence.—*Illinois Health Messenger*, 5:85-86 (Nov. 15), 1933.

PUBLIC HEALTH ENGINEERING

MOSQUITOES HAVE NO PLACE IN THE CITY*

R. E. TARBETT

Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

URBAN mosquito control combines two types of activity: the control over production of "wild" mosquitoes of various species breeding in natural water collections in undeveloped areas within and adjacent to the built-up section; and control over production of the "domestic" and pestiferous species, breeding in the innumerable small permanent and temporary collections of water whose origin is due to the development of the city and to the habits and characteristics of the population.

In general, the problem in any large urban community is one of pest control, although control of production of malaria carrying mosquitoes may be necessary in the outlying sections, and in the South control over production of *Aedes aegypti*. In the case of *A. aegypti* it is both a public health and a pest or nuisance problem.

The development of urban areas tends to build out the mosquito life originally there, but at the same time builds in the domestic types of mosquitoes.

The mosquitoes which constitute the greatest nuisance in our urban areas are certain species of the *Culex* group, commonly known as domestic or house mosquitoes and, in the South, the most domestic of all, the *Aedes aegypti*. The

Culex group will breed in any and all collections of water suitably protected, but appear to prefer a filthy water. The *A. aegypti* will breed only in man-made containers in and around inhabited dwellings.

The number of small active foci of mosquito production, all man-made, that exist in an urban area is almost unbelievable. Some of these may be of a permanent character but many are temporary and are constantly changing. Some of these are street corner catch basins, particularly those that are trapped; areaway catch basins and traps including garage traps; temporary or semi-permanent collections of water due to obstruction of natural water courses, and the various and sundry receptacles and things that will hold small quantities of water for a period of 7 to 10 days.

Location near extensive salt marsh areas may complicate the problem, since these areas may permit production in large numbers of the very troublesome, long flight species of mosquitoes.

In the control of mosquito production in natural water areas we have to deal only with the mosquito and the breeding places. In urban control, however, we have added the human factor which greatly complicates the problem. Because of this the inspection service is one of the most important parts of the control activity.

Cost of mosquito control in large

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 19, 1935.

Gas killing mosquito trap—operated automatically by clock attachment on storage battery current

urban areas is not relatively expensive, and the relief from mosquito nuisance generally warrants the expense.

Unit costs will vary depending upon the location and character of the city as well as the extent of the area within which control activity must be maintained. In general, the cost for the first year of control should not exceed \$.10 per capita, or \$600 to \$650 per square mile, for a city of 500,000 population. This should decrease somewhat with larger cities and increase with smaller ones. After the first year the cost should drop to about \$.06 per capita, or \$400 to \$450 per square mile of urban area, for the 500,000 population city, varying as before with the increase or decrease from that figure.

Where large swampy areas or salt marsh areas adjoin the city, the first cost of control would be considerably increased, but it would not be recom-

mended that all necessary drainage be attempted the first year.

It is not possible to go into the details and complications of urban control. Two things are important. Within the city proper constant and proper inspection of all properties, public as well as private, must be maintained if the ever changing sources of production are to be controlled. Exact knowledge as to the species of mosquitoes found in the area, as well as their characteristics in that particular area, must be had, and the density of species checked regularly in all sections of the area. With this information it is possible so to plan the work as to bring about a reduced production sufficient to maintain prevalence below the nuisance point.

In urban control there is perhaps more opportunity for development of methods and equipment than in the case of control in rural areas. Many things may affect the movement of

Glass killing mosquito trap

mosquitoes within urban areas that do not exist in rural areas. Air currents are different; light attraction exists; certain areas have an abundance of harborage while others have an excess of moisture. With a combination of some of these conditions we may find an excess prevalence in areas considerably removed from breeding areas.

In determining the relative prevalence of mosquitoes as well as the species present in any section, the mosquito trap developed at the New Jersey Agricultural Experiment Station is of considerable assistance. This trap does not depend upon the human equation which must enter into all hand catching methods. It is automatically controlled by a time-clock so that it may be in operation during any definite period of time. It has been found that mosquitoes not ordinarily obtained by hand catching are collected in this trap. We furthermore know that when mosquitoes collected by the trap during the dusk and dawn periods, say from 6 to 9 in the evening and 4 to 6 in the morning, exceed 24, a nuisance exists. By proper use of these traps it is

possible constantly to maintain definite knowledge as to mosquito prevalence as well as species, and to direct the work in those sections where excess prevalence exists.

Motorcycle catch-basin spraying unit

At times there are indications that flights of mosquitoes are taking place into certain definite areas, and where this occurs a flight detector may be of considerable value in determining from what direction this flight is coming. With the direction established it is not difficult generally to locate the source.

Boat spraying unit in operation

In the general control over many breeding places within the city which cannot be done away with, we have not been able to improve upon oil as a larvicide. The application of this oil, and usually it must be applied at approximately 7-day intervals, offers opportunity for development of methods and equipment which will bring the cost to a minimum. An example of this is perhaps in the catch basin control in the City of Washington. Over 10,000 trapped catch basins exist in which water is maintained at all times. In these catch basins we have found that *Culex* mosquitoes will breed in enormous quantities. Motorcycle equipment has been developed for carrying on this work. With this equipment it has been possible for one man to care for about 450 catch basins per day at a cost of approximately \$.015 per catch basin oiling. Attempts have been made to develop other methods of control which would further reduce the cost. On the basis of \$.40 to \$.45 per season, however, it has thus far been difficult to lower the expense.

Another problem which was encountered in Washington and which might be encountered in other cities, particularly those located on navigable

waters, is the hydraulic filling of marsh areas. In the filling operation, constantly changing water areas are created and generally the filled area is so soft that men cannot enter upon it. These areas may be controlled with the minimum amount of expense through spraying a water and oil mixture by means of a force pump installed in a bateau. With this apparatus it is possible to throw a stream of water mixed with oil a distance of 60 ft. from the end of a 500 ft. hose.

These two methods of applying oil in specific cases are given as illustrations of what may be developed to take care economically of certain breeding areas, which may be peculiar to any area.

Mosquito nuisance in a large urban area is due principally to causes brought about through the development of the city, and to the character of the city, and have little connection with conditions existent prior to development. Since conditions permitting the nuisance are man-made, the control should be considered as much a part of municipal activities as is garbage collection, for instance. Since mosquito nuisance is no more excusable than other nuisances, there should be no reason for permitting its existence.

INDUSTRIAL HYGIENE

The Influence of Atmospheric Ionization Upon the Human Organism—The physiologic effect of the ionic content of the air on the normal human organism was investigated in this study. Observations made on five normal subjects once a week over a period of 1 year showed no significant changes in the metabolic rate, blood pressure, pulse rate, respiration, oral, skin and body temperature, although under certain conditions, changes in at-

mospheric ionization appeared to be associated with minor physiologic changes.

Breathing artificially de-ionized air for a period of 1 hour has no apparent effect on a subject under basal conditions.—A. D. Brandt. *J. Indust. Hyg.* 15, 5:354-361 (Sept.), 1933. L. G.

The Effect of Clothing on the Rate of Cooling of the Body—This is a theoretical discussion of the effect

of clothing on the rate of cooling of the body. The naked and clothed body in still and moving air is considered, and formulae for the rate of cooling are developed in each case.

Analyses of the derived expressions show the following: A given air motion cannot cause as large a percentage increase in cooling on the clothed body as on the naked body; a greater increase in the cooling rate may be had by the removal of clothing than by an increase in air velocity when the over-all conduction of the clothing is less than the air flow coefficient for still air; and the rate of cooling of either a clothed or naked body, under constant conditions regarding clothing and air motion, is proportional to the difference between the skin temperature and the dry bulb temperature of the air.—Walter S. Weeks. *J. Indust. Hyg.* 15, 5:383-386 (Sept.), 1933. L. G.

Measurement of the Flow of Air Through Registers and Grilles—This study develops a method of measurement of air flow by the use of the anemometer which is applicable to field tests where a precision of 5 per cent may be considered reasonable. Several types of grille are considered in the investigation. Pitot tube traverses were taken as a basis of comparison of the method used.

The formula $V = \frac{C_r \cdot v(A+a)}{Z}$ (Where V = volume of air in cu. ft. per minute; C_r = velocity coefficient varying between 0.952 at 150 ft. per minute to 1.000 at velocity of 800 ft. per minute, v = average indicated velocity in ft. per minute obtained by anemometer traverse, A = gross area or grille in sq. ft.; a = net free area in sq. ft.) was found to be applicable under normal conditions and procedure for supply grilles, but a second coefficient was necessary when the frets of the grilles were large. The value of the fret

coefficient, C_r , varies between 0.65 to 1.00 and is a function of the percentage of free area, size of fret and size of anemometer used.

The four methods of making an anemometer traverse, namely, (1) spot traverse—stationary reading; (2) over-all moving traverse; (3) spot traverse—moving reading; and (4) strip traverse, are discussed. With proper care all the methods gave substantially the same results.

The effect of approach on the character of the air stream is considered. Narrow strips of dead space may usually be ignored without appreciable error in the results but it is recommended that the quiescent area be omitted in the calculations of air flow.

Difficulty was encountered in velocity measurements of unit ventilators due to poor air distribution. A new method of measurement was therefore devised using a sheet-metal cone-cylinder attachment on the anemometers so as to obtain a uniform velocity against the whole area of the anemometer. This device is also applicable to the measurement of air flow in grilles of a highly ornamental pattern where it is difficult to measure accurately the free area of the outlet.

The disadvantage of this instrument is that it is sensitive to variations in the angle of flow. It is believed that the accuracy of the device may be increased by further developments.—L. E. Davies. *Heating, Piping and Air Conditioning*, 5, 9:486-495 (Sept.), 1933. L. G.

Radiation of Energy Through Glass—This is a study of low temperature radiation through glass. The absorbing qualities of various kinds of glass was determined with the pyroheliometer. Several radiant energy sources such as a radiant heater, an electric arc and banks of incandescent tungsten and carbon filament bulbs were used.

The results of the investigation showed that glass does not transmit low temperature radiation. Ordinary double strength window glass transmits no measurable amount of energy radiated from a source at 500° F., or lower. Only 6.0 and 12.3 per cent of the total radiation is transmitted from surfaces of 700° F. and 1,000° F. respectively. The same glass, however, transmits 76.3 per cent of the radiation from an incandescent tungsten lamp, 65.7 per cent of the radiation from an arc lamp and 88.9 per cent of the radiation from the sun. Glass windows may therefore constitute heat traps since they allow a relatively free transmission of radiant energy into the room from the sun to warm the objects in it, but do not allow these objects to lose this heat by re-radiation through the windows.—J. E. Blackshaw and F. C. Houghten. *Heating, Piping and Air Conditioning*, 5, 10:523-525 (Oct.), 1933.

L. G.

On the Normal Absorption and Excretion of Lead. I. Lead Absorption and Excretion in Primitive Life—The presence of "normal" lead in human tissues has been a subject of controversy since 1838, but with improved methods for the estimation of lead it is now apparent that lead occurs regularly in the feces and in the urine, as well as in the tissues of normal, healthy persons. It was generally believed that the presence of lead in the normal body arose from contact with lead-containing commodities of modern life. Observations were therefore made in two communities in Mexico to test this hypothesis. The two chosen communities prescribed no opportunities for artificial lead exposure and represented conditions of primitive life. The only metal implements used consisted of sickles and machetes.

Blood, feces, and urine samples were taken from each of the 95 subjects se-

lected for study. Beverages and food, as well as soil samples from the pueblos, were also analyzed. The results showed that the soil samples from various parts of the fields under cultivation yielded lead in concentrations between 0.60 to 6.00 mg. per kg.; water contained minute traces of lead; vegetation disclosed small amounts ranging from 0.03 to 0.94 mg. per kg.; lead in animal products and prepared food materials varied between 0.02 to 4.15 mg. per kg. The lead-glazed character of the pottery used may possibly account for the high concentration of lead in the prepared food. Urine analyses showed the mean concentration of lead to be 0.0138 mg. per liter of urine. The mean concentration of lead in the feces was 0.1078 mg. per sample of feces or 0.0347 mg. per gm. of ash. Blood analyses showed small amounts of lead. Sixty-five per cent of the blood samples were negative for lead content while 35 per cent showed concentrations from 0.01 to 0.06 mg. of lead per 100 gm. of blood.

A detailed description of the analytical methods used in the analysis of urine, feces, food, tissue and other materials is given.—Robert A. Kehoe, Frederick Thamann, and Jacob Cholak. *J. Indust. Hyg.* XV, 5:257-271 (Sept.), 1933.

L. G.

On the Normal Absorption and Excretion of Lead. II. Lead Absorption and Lead Excretion in Modern American Life—This is a study of the lead intake and output of human subjects under normal environmental conditions. The results showed that the lead intake in the food of the selected subjects was approximately equivalent to the lead content of their feces and varied between 0.16 mg. to 0.28 mg. of lead per day; that the normal American adult excreted lead at a rate of from 0.02 to 0.08 mg. per liter of urine, and from 0.03 to 0.1 mg.

per gm. of ash in the feces; that the greater part of the lead administered orally was eliminated unabsorbed and that such amounts of lead which were absorbed produced an increase in the rate of urinary excretion during the period of active absorption and for a time thereafter.

Lead determination of the various tissues of the human body was also made. In the case of a normal child the greatest concentration of lead (1.142 and 1.022 of lead per 100 gm.) was found in the long and flat bone. The average lead concentration was 0.309 mg. per 100 gm. of tissue. The analysis of the tissues of a normal adult showed the greatest concentration (1.11 mg. of lead per 100 gm.) in the flat bone and an average lead concentration of 0.17 mg. per 100 gm. of tissue.—Robert Kehoe, Frederick Thammann, and Jacob Cholak. *J. Indust. Hyg.* 15, 5:273-288 (Sept.), 1933.

L. G.

On the Normal Absorption and Excretion of Lead. III. The Sources of Normal Lead Absorption—Previous studies have shown that the presence of lead in food materials was the major factor in the lead absorption and lead excretion of normal persons. Certain common foods and beverages were therefore analyzed for lead content. It was found that food which was largely of natural origin contained insignificant amounts of lead (0.00 to 0.11 mg. of lead per kg.) while the staple articles furnished large amounts of lead. It was found that fruits which were analyzed without removing the peel showed a high concentration of lead, the source obviously being from the wide use of lead compounds as insecticides.

On the basis of the amount of material consumed by an individual per week, meat and bread furnished one-fourth to one-third of the average

amount of lead ingested weekly. When milk occupied a prominent position in the dietary it was found that it contributed a large proportion of lead. The concentration of lead in milk, however, did at no time exceed 0.04 mg. per liter.

Beverages, other than water, showed significant concentrations of lead. Synthetic lemonade, carbonated drinks, grape juice, and alcoholic beverages showed the presence of varying amounts of lead which were due to some form of contamination and not to the lead content of the beverage, *per se*.

An excellent bibliography on the sources of lead is presented.—Robert Kehoe, Frederick Thammann, and Jacob Cholak. *J. Indust. Hyg.* 15, 5:290-300 (Sept.), 1933.

L. G.

On the Normal Absorption and Excretion of Lead. IV. Lead Absorption and Excretion in Infants and Children—In order to determine whether limited length and variety of experience was associated with a corresponding limitation of lead absorption and excretion, studies were made on a group of infants and children. A group of American children with no lead exposure showed a much higher concentration of lead in the urine and feces than a group of Mexican children living under essentially primitive conditions. The American group showed concentrations varying from 0.02 to 0.18 mg. per liter of urine, with a mean excretion of 0.08 mg. per liter, as compared with the Mexican group which varied from nil to 0.03 mg. per liter; with a mean of 0.015 mg. per liter. The mean lead excretion in the feces of the American group was twice that of the Mexicans, with 0.08 mg. per gm. of ash. No correlation was found between lead excretion and age.

Analyses of human milk from normal mothers with negative histories of occupational lead exposure showed that

ingestion of human milk is one source of lead intake. Amounts varying from 1.0 to 0.05 mg. per liter were found.

In order to test the possibility of the presence of lead in infants being due to lead absorption in utero, the tissues of premature and stillborn fetuses were analyzed for lead content. Varying amounts of lead were found in the various tissues but the amounts found were too small to account for a rate of lead excretion such as that observed in infants and children.—Robert A. Kehoe, Frederick Thamann and Jacob Cholak. *J. Indust. Hyg.* 15, 5:301–305 (Sept.), 1933. L. G.

Lead Absorption in Relation to the Diagnosis of Lead Poisoning—In recent years the presence of lead in the feces and urine of suspected cases of lead poisoning has been used as one of the criteria of lead exposure. The assumption was that an exposure to lead resulted in lead absorption and produced an elevated rate of lead excretion for some time after exposure had ceased. The lead excretion of subjects after cessation of lead exposure was therefore followed to determine the validity of such an assumption.

In the present study it was found that after cessation of lead exposure, lead is excreted at a higher rate than normal when abnormal amounts of lead are absorbed. The period of increased lead excretion depends upon the extent of lead absorption; the rate of lead output diminishes rapidly for a period of several weeks after which there is a prolonged and gradual diminution in the excretory rate until the normal level is reached. Following an abnormal lead exposure unusual amounts of lead were found in the blood during life and in the tissues at necropsy for variable periods of time after cessation of exposure.

The detection of abnormally high rates of lead excretion is a very valu-

able aid in determining the severity of lead exposure, but it does not constitute a diagnosis of lead intoxication. Skill and judgment in the interpretation of clinical evidence is still the basis of the diagnosis.—Robert A. Kehoe, Frederick Thamann and Jacob Cholak.—*J. Indust. Hyg.* 15, 5, 320–340 (Sept.), 1933. L. G.

Health Aspects of Radium Dial Painting. I. Scope and Findings—This report is the result of investigations conducted in the radium dial painting industry. This report consists of findings and recommendations. Seven factories were studied; 14 men and 228 women were examined. In the analysis the female radium workers were divided into two groups, one group consisted of workers who were exposed to radioactive substances before pointing the brush with the mouth was prohibited in every plant and the second group contained those workers who have been exposed to radium only under the new conditions. The results of the study indicated that the abolition of pointing the brush with the mouth has not entirely solved the problem of radium deposition in the body.

Tests demonstrated the presence of radioactive substances in the air of the workrooms. An average of 9.8×10^{-10} gm. of radium per 10 cu. m. of air was detected. The average gamma exposure of the workers was equivalent to that which would be produced by about 1 mm. of radium 50 cm. from a worker.

Twenty-eight recommendations are made for minimizing the hazard in radium dial painting. These suggestions pertain to factory cleanliness, personal cleanliness of the workers, protection of workers by means of screens and hoods, and adequate ventilation.—Louis Schwartz, Fred L. Knowles, Rollo H. Britton and Lewis R. Thompson.—*J. Indust. Hyg.* 15, 5:363–367 (Sept.), 1933. L. G.

Lead Absorption and Excretion in Certain Trades—This investigation consists of the study of lead excretion of workers in manufacturing plants when lead is involved. The results may be tabulated as follows:

		Mean Lead Concentration in Milligrams		
	Degree of Exposure	White Lead Mfg. plant	Elec. Storage Battery plant	Tetraethyl Lead Mfg. plant
Feces (per gram Ash)	Severe Exposure	0.870	0.70	0.201
	Moderate "		0.52	
	Mild "		0.22	
	Average "	0.573	0.45	0.186
Urine (per liter)	Severe Exposure	0.336	0.330	0.198
	Moderate "		0.176	
	Mild "		0.124	
	Average "	0.241	0.182	0.129

Clinical lead poisoning was observed in the white lead manufacturing plant and in the storage battery plant, while the tetraethyl lead plant had no such histories during a 5-year period of observation.

The rate of urinary lead excretion varies with the rate of lead absorption in normal persons without occupational lead exposure but increased exposure fails to bring about a corresponding increase in the urinary excretory rate. It is believed that lead exposure is safe if the mean lead excretion is not more than 0.6 mg. per day in the feces and 0.15 mg. per liter in the urine. If conditions are such that lead is excreted at a mean rate above 1.1 mg. per day in the feces and 0.21 mg. per liter in the urine, cases of lead poisoning may be expected to occur among exposed workers.—Robert A. Kehoe, Frederick Thamann and Jacob Cholak. *J. Indust. Hyg.* 15, 5:306-319 (Sept.), 1933.

L. G.

Health Aspects of Radium Dial Painting. II. Occupational Environment—The occupational environment of radium dial painting is dis-

cussed in this paper. This includes a history of the radium dial processes; a description and analysis of the occupation; and a sanitary survey of 7 radium dial painting plants.

Radioactive dust determinations were

made by taking atmospheric dust samples in paper thimbles as a collecting medium at a rate of 2 cu. ft. per minute. The analyses showed an average exposure of 26.1×10^{-10} gm. of radium per 10 cu. m. of air for dial painters as compared to 9.8×10^{-10} gm. per 10 cu. m. of air for the general air of the room. The occupation of radium dusting gave the highest average concentration of 169.3×10^{-10} gm. per 10 cu. m. Considerable variations in the average radium exposure were noted in different plants for the same occupation.

Electroscopic determinations of the amounts of gamma and beta radiations and of radon were also made. The gamma radiation was found to be equivalent to the discharge produced by about 1,200 micrograms of radium 50 cm. from the instrument and the beta equivalent was 2,100 micrograms of radium. The radon readings gave an average of 51 curies $\times 10^{-8}$ per 10 cu. m. of air which was about 2,000 times the content of normal outdoor air.—J. J. Bloomfield and F. L. Knowles. *J. Indust. Hyg.*, 15, 5:368-382 (Sept.), 1933.

L. G.

FOOD AND NUTRITION

The Stability of Vitamin A in Cod Liver Oil Emulsions—The possibility of considerable destruction of vitamin A in cod liver oil on emulsification with gum acacia through the action of peroxidase in the gum acacia and the exposure of a considerable surface of the oil to air during homogenization was tested by preparing five different emulsions of cod liver oil, allowing them to stand in well corked amber bottles in a dark cupboard for varying periods of from 2 days to 15 months, recovering the oils from the emulsions, and testing them by the colorimetric procedure of Drummond and Hilditch (E.S.R., 64, p. 694).

The emulsions included two with gum acacia and 50 per cent cod liver oil and two with gum tragacanth (containing no peroxidase) and 25 per cent cod liver oil, one of each being homogenized and the other not homogenized. Another emulsion was made with gum acacia previously heated at 100° C. for 1 hour to destroy peroxidase and 50 per cent cod liver oil and not homogenized. Samples of the cod liver oil and the homogenized emulsion with gum acacia were also tested spectrographically by R. A. Morton at the beginning of the experiment and after 7 months.

No loss in vitamin A potency could be detected in the original oil or any of the emulsions for at least 4 months. At 6 months there was some evidence of change, particularly in the original oil. At 7 months the change was evident in all of the gum acacia emulsions and the non-homogenized gum tragacanth emulsion, and from that time onward in all of the samples. The spectrographic studies likewise showed no

greater deterioration in the emulsified oils than in the original oil.

The authors conclude that the procedure followed in manufacturing emulsions of cod liver oil does not diminish the natural stability of the vitamin A in the oil itself during storage, and that "cod liver oil emulsions can be kept for at least 4 months without appreciable loss of vitamin A potency, and probably for 7 or 8 months without serious alteration therein, if stored in well stoppered, amber glass bottles and kept in the dark."—H. N. Griffiths, T. P. Hilditch and J. Rae, *Analyst*, 58:65, 1933; *Abstr., Exper. Sta. Rec.* 69:759 (Nov.), 1933.

Losses of Vitamin A in Drying Fresh Raw Carrots and Sweet Potatoes and Canned Spinach—In this experiment, the vitamin A content of dried carrots, sweet potatoes and spinach was compared with the vitamin A content of the raw carrots, canned spinach, and raw sweet potatoes. Sixteen groups of rats were used in the experiment. The material tested was fed twice a week. The raw yellow carrots contained approximately 43 units of vitamin A per gm. of raw fresh material containing 11.4 per cent dry matter. Approximately 80 per cent of the vitamin A content was lost during drying. The raw sweet potatoes contained approximately 20 units of vitamin A per gm., while the loss of vitamin A on drying was 29 per cent. The canned spinach contained 140 units of vitamin A, while the loss on drying was 65 per cent.

While these results do not disclose whether there is a loss of vitamin A

on storage, they do show that stored fresh food or canned food may be higher in vitamin A than the dried material.—G. S. Fraps and Ray Treichler, *J. Agri. Res.* 47:539 (Oct. 1), 1933.

The Vitamin A Content of Pimiento Pepper—In determining the vitamin A value of the pimiento pepper, three series of experiments were run: first, on the fresh pepper; second, on the canned pepper; and third, on the dried pepper. The fresh peppers were kept in hydrators under refrigeration; the canned were commercially canned; and the dried material was prepared by coring the pods, cutting, pressing, washing, and after a second pressing, drying at 38° C., finely grinding and packing under vacuum.

Rats were depleted of vitamin A, but vitamin D sufficiency was maintained by viosterol. Standard carotene obtained from the Bureau of Chemistry and Soils, U. S. Department of Agriculture, was dissolved in Wesson oil and stock solutions made up so that 0.5 c.c. contained respectively 0.002 mg. and 0.006 mg. of carotene. Carotene was determined in the pepper as 0.33 gm. per kg. of dried material. Carotene content in the fresh and canned pimiento was computed. The daily intake was from 0.00033 to 0.00132 in the dried pepper, 0.00043 to 0.00086 in the canned pepper, and 0.00135 to 0.00251 in the fresh pepper. Carotene was fed at the 0.001 mg. and 0.003 mg. level. The growth response on the same levels are comparable and the figures indicate that the unit for dried pepper lies under 2 mg. but it is not established that it is as low as 1 mg.—Leah Ascham, Georgia Experiment Station, *Bull.* 177, Sept., 1933.

The Vitamin C Content of Commercially Canned Sauerkraut Produced Under Known Conditions—This reports a continuation of a study

previously reported on the antiscorbutic value of commercially canned sauerkraut. In the former study (*J. Agri. Res.* 41:51, 1930), six commercial brands were used, and data here represent 4 of the 6 previously reported, eliminating the two which scored highest for vitamin C. Of the 4 samples of the sauerkraut, 3 were machine packed and 1 hand packed. The acidity expressed as lactic acid varied in the cans examined, from a minimum of 1.10 per cent to a maximum of 1.49 per cent. The pH value in all cases was 5.2.

The ration used as a negative control resulted in the development of pronounced scurvy in 16 days, but prevention of scurvy in the positive controls resulted with either 5 gm. or 2½ gm. daily intake of raw cabbage. Of the 4 brands tested with 10, 7½, 5 and 2½ gm. daily doses, 2 of the brands were found to contain a definite amount of vitamin C, complete protection being secured with 7½ and 5 gm. in one sample and 10 and 7½ gm. in the other. Two and one-half gm. doses failed to protect in either of these two brands. A 5 gm. daily intake did not protect in one of the brands. Two other brands failed to give protection at any level including the 10 gm. daily intake. Scurvy occurred just as quickly with these two canned sauerkraut supplements as in the negative controls.

Although the details of the manufacture and canning of the sauerkraut show no common factors which would account for the great difference in the antiscorbutic value, it is significant that the two brands in this experiment which show a definite protective value repeated the results shown by these same two brands in the former work.

In the two brands which rated highest, the same variety of cabbage was used for the sauerkraut, but in one of the cans showing no protection against scurvy 70 per cent of the cabbage was

of this same variety. The authors attribute the differences to some undetected factor or factors not disclosed in the experiment which may be dependent upon the manufacturing procedure.—Helen T. Parsons and Carolyn Horn, *J. Agri. Res.* 47:627 (Oct. 15), 1933.

Growth of Rats Fed High Protein Rations Supplemented by Different Amounts and Combinations of Vitamins B (B₁), G (B₂), and B Complex—Although high protein diets are conceded as adequate for carnivora, the literature shows conflicting reports in the case of omnivora and herbivora, both normal and subnormal rates of growth being reported on rations containing 45 to 95 per cent of casein.

The investigation here reported undertook to answer this question also as to the reported need for increasing B vitamins in animals on high protein rations. The data include rats used in another experiment in which they had been subjected to a right unilateral nephrectomy. In these cases the controls were similarly nephrectomized. Casein was fed *ad libitum* at 18, 50, and 90 per cent levels, including vitamin-bearing adjuvants, supplemented with daily allowance of cod liver oil and wheat germ oil. The vitamins B, G, and B complex were supplemented by dried yeast, tikitiki extract, and autoclaved yeast.

As shown by mean gains in weight, there was no difference between the nephrectomized rats and those which had both kidneys intact in any one of the 3 levels of casein employed. Ninety per cent of casein plus 0.4 gm. of yeast produced inferior growth in both nephrectomized and intact rats compared to controls. Increasing the protein allowance equalized the growth between the intact and controls but resulted in inferior gains for the nephrectomized rats compared to their controls.

Rats on the 50 per cent level grew as well as controls on 18 per cent of this protein and better than those on the 90 per cent level. The optimum level for protein for rapid growth is probably between 18 and 50 per cent. The need of rats on high protein diets for increased amounts of B and G vitamins is not apparent where yeast alone is the source for 0.8 gm. of yeast produced better results than either one-half or twice that amount.

Supplementing either the controls or the high protein diets in the absence of yeast, with a maximum of vitamin G from autoclaved yeast and a minimum of vitamin B from tikitiki extract or the reverse of these vitamin substances, resulted in an unsatisfactory growth response.

From the data on a small number of rats, there is an indication of better utilization for growth of the rich protein diets than in the case of a ration containing 18 per cent casein.—Lillias D. Francis, Arthur H. Smith, and Lafayette B. Mendel, *J. Nutrition*, 6:493 (Nov.), 1933.

Destruction and Survival of Microorganisms in Frozen Pack Foods—Experiments are reported concerning the fate of microorganisms in berries and vegetables held under different conditions of oxygen environment and low temperature storage, together with observations on the effects of CO₂ of respiration on microorganisms in packs of berries and in artificial media. The storage periods used varied from 14 weeks to 2 years.

A series of storage experiments are presented on berries packed in sucrose solutions of different concentrations and stored in paraffined paper cups and in cans both vacuumed and without vacuum for periods extending from 14 weeks to 13 months at temperatures from -2° C. to -20° C.

In this experiment it was demon-

strated that there was a much less rapid decrease in bacterial numbers at -20° C. than at -10° C. regardless of whether the container was airtight or not. There was a rapid increase of microorganisms in non-airtight containers, and a decrease in sealed containers at -2° C. and -4° C. A more rapid decrease in microorganisms was observed in sealed than in non-airtight containers at -10° C. and -7° C. It is suggested that these phenomena are in part explainable on the ground that in sealed containers of fresh fruit the evolution of CO_2 previous to the ice formation exerts a destructive influence on the microorganisms.

Containers of fruit heated to prevent evolution of CO_2 failed to show appreciable decrease in microorganisms. Cultures of molds, torulae and yeasts subjected to various freezing storage temperatures in suitable liquid media, showed that the death rates at -6° C. are lower and at -10° C. slightly higher than at -20° C. *Cladosporium* was capable of growth at -2° C. while *oidium* and *torula* at -4° C. on small fruit in non-airtight containers.

Of interest to public health workers and food control officials is the persistence of lactobacilli and members of the colon-aerogenes group of bacteria, chiefly genus *Aerobacter* observed in connection with the studies of freezing storage of vegetables. Evidence is presented that lactobacilli and to a lesser extent "colon-group" organisms persist in peas for at least 2 years at -10° C. and that "colon" organisms in string beans and spinach at -10° C. for at least 19 months and 10 months respectively. It was also observed that bacteria presumably of the genus *Pseudomonas* showed a definite increase in peas stored at -4° C.

A study of the destructive effect of ice formation on yeasts was presented in which the organisms suspended in wort were stored in both liquid and frozen conditions at -10° C. A much more rapid decrease of viable cells was shown in the frozen than in the unfrozen liquid wort indicating the destructive effect of ice-formation on the test organisms.—J. A. Berry, *J. Bact.* 26:459 (Nov.), 1933.

The Stimulating Action of Copper on Erythropoiesis—Albino rats were taken from their mothers when 21 days old and kept on a diet of evaporated milk, or of raw milk supplemented with copper in some cases. The copper was fed as copper sulphate in an aqueous solution of such strength that 0.5 c.c. contained 0.25 mg. of copper, or, if less copper was used, 0.025 mg. The animals were weighed weekly, and hemoglobin determinations and erythrocyte counts made biweekly at first and then weekly.

The rats which were fed raw milk alone showed a sharp fall in hemoglobin and red cell count, while the animals fed diluted evaporated milk showed a less rapid fall in hemoglobin but an increase in erythrocytes. When copper without iron was fed as a supplement to raw milk, results similar to those with evaporated milk were obtained, indicating that the copper in the evaporated milk is responsible for the temporary maintenance of a high erythrocyte count.

When given as a supplement to the milk diet of anemic rats, copper ranging in amounts from 0.025 mg. to 0.5 mg. daily shows a definite erythropoietic action without any influence on hemoglobin formation.—Hermann B. Stein and Robert C. Lewis, *J. Nutrition*, 6:465 (Sept.), 1933.

CHILD HYGIENE

CHILD WELFARE IN GERMANY

RICHARD ARTHUR BOLT, M.D., Dr.P.H., F.A.P.H.A.

Director, Cleveland Child Health Association

*At Present on Oberlaender Trust Award to Study Child Health
and Welfare in Germany and Austria*

THE reorganization of public health and child welfare in Germany under the new government has progressed far enough to discern its main lines of development and to make possible a sketch of the present phases of that development. It should be grasped at the very beginning that the "Revolution" is over and that the "Third Reich" under the supreme command of Reichcounsellor Adolph Hitler and his small group of advisers is an accomplished fact. The political changes which have recently taken place all tend toward a highly centralized state, although in its administrative control considerable latitude within the general regulations is allowed for local conditions. This shift in control has affected every phase of political, social, economic, and educational life in Germany. It is now being applied with vigor to the welfare and public health fields. Centralization and uniformity of control appear to be the watchwords.

Hitler has repeatedly stressed the importance of working for the good of a whole united Germany. "Each for all and all for each" is a favorite slogan which has captured the masses. His speeches ring with an assurance that he has in mind the welfare of the entire population and not benefits to any privileged classes.

Considerable attention is now being given to ways and means of strengthen-

ing family ties. To this end the maternity and child welfare measures so well conceived and worked out during the past 25 years in Germany are being taken over in their entirety and incorporated in the new schemes. Several pieces of recent legislation are of considerable interest in indicating present trends. Provisions have been made to encourage at least 200,000 couples to marry annually by promising to advance to each couple 1000 reich marks with which to help furnish their homes. This sum must be repaid in easy installments with the exception that the government will not require 250 marks for each child which the family may have. Provisions to protect the pregnant woman and to provide for her welfare before, during and after confinement are being strengthened. The premium given to those who nurse their babies at the breast during the first three months is also to be continued. There is widespread, persistent and attractive propaganda to idealize family life and to urge the propagation of healthy offspring. Birth control from its contraceptive side is frowned upon. On the other hand positive measures to cut down the propagation of unfit stock have been seriously proposed. The recent so-called "eugenic sterilization law" which has been promulgated makes it obligatory for physicians and institutions to report to a specially created "Amt" or Bureau all cases of feeble-

mindfulness, insanity, schizophrenia, chronic alcoholism, and other mental disorders. The individuals may submit voluntarily to the most approved methods of sterilization, or if they do not submit and are judged suitable subjects for sterilization by special boards, they will be forcibly subjected to sterilization. The machinery for this act is already being assembled. It is stated that by January 1, 1934, the whole legislation will become effective. This is by far the most radical step taken by any nation in attempting to eliminate the "unfit." It has already stirred up considerable criticism and protests from outside Germany. The German press, strictly censored, of course, has come unitedly to its support. Private conversations with professional men reveal difference of opinion as to whether it can be carried out successfully.

The latest measure of medical and public health interest is the promulgation by Minister Goering of an order forbidding vivisection. Goering in a radio speech stated that this is not intended to hamper scientific research or modern medical needs, but that all animals submitted to experiment must be thoroughly anesthetized and that any "unnecessary cruelty" will be punished. Just how far these regulations will actually affect the experimental work now being carried out in the laboratories of Germany it is difficult to state.

Another change which has taken place recently is the consolidation under one administrative head of all physicians working in any capacity in the child welfare or child hygiene stations in Greater Berlin. As the new Director expressed it, "There will no longer be infant welfare doctors, preschool doctors, and school doctors, but each doctor will be expected to handle family problems of health in children of whatever age. The family practice must be the unit."

There has undoubtedly come about a considerable distrust for the professional social worker. One man close to governmental affairs remarked that the new administration will use as few such workers as possible and depend more upon enlisting the interest and help of voluntary workers who knew the social and family problems in their immediate neighborhoods. There is a strong feeling that other technically trained workers such as physicians, trained nurses, and public health officials are in a better position to judge of the social conditions than professional social workers. Many of the new regimen appear to distrust social workers who, they feel, have tended to radical, socialistic, or communistic ideas and therefore have no place in the new order.

While there are still a considerable number of day nurseries operating in the larger centers of population the new administration seems to consider them but temporary expedients. Nursery schools have never attained the position in Germany that they have in England and the United States. Again one hears it expressed by those sympathetic to the new regimen, that the money used to support day nurseries and kindergartens had better be applied directly to the homes where the mothers should be encouraged to remain and look after their young children. This of course is only another version of the old slogan that, "the place of the woman is in the home."

The child welfare centers, of which there are many in the larger cities, continue to take children from birth until school entrance. The centers which have thus far been visited appear to be working at full pressure with very devoted staffs. There have been many changes in personnel in these centers and the question naturally arises, "Will the new professional and voluntary workers bring to the work the same skill

and devotion as the old? " Only time will permit of an answer to this question.

From all that can be gathered regarding the condition of the younger children, they appear on the whole in good condition. Even in families provided for on governmental and municipal "dole" the children seem to be well fed and happy in their play. A visit to one of the largest welfare distribution centers in Berlin revealed a surprisingly neat, orderly, and expectantly hopeful lot of people receiving material relief. One does not see the abject poverty, beggary, and degraded condition of the people as noted in many of our American cities during the depression. Provision is made to supply essential fats and milk for the children as a first item on the dietary.

It is true, however, as a number of physicians have vouched for it and has been noted by direct observation, that the children between 3 and 6 years of age appear to be undernourished in many instances. On the other hand, the school children and especially those of adolescent age seem to be in excellent condition. One of the amazing things in Germany is the great enthusiasm of the youth for the new regimen. The

Youth Movement has developed a marked idealism. Hitler is worshipped as a hero by all classes of youth. The buoyant, joyous, hopeful life of present-day youth of Germany is one of the marked features of the new regime. The outdoor life with its regimentation, simple but wholesome food, exposure to sun and active sports is surely creating a vigorous young manhood and womanhood, whatever its by-products may be.

One of the most interesting revelations to an American is the more or less general acceptance by German physicians of the idea that the nutritional status of the baby and young child largely determines its immunity against a number of the infectious diseases. There is not much enthusiasm for toxin-antitoxin or toxoid in Germany. Anti-toxin is used in the institutions as an immediate prophylactic and curative agent but the widespread use of T.A.T. such as in the United States does not appear. The unfortunate Lubeck affair has of course influenced many physicians to caution. Immunization against tuberculosis has received a complete setback in Germany.

Vienna, Austria

November 2, 1933.

PUBLIC HEALTH NURSING*

A Tip for School Nurses and Health Education Teachers — M. Barbara Dee of Boston says in the November (1933) *Hygeia* that for some years she has conducted a health class for high school girls by the old stereotyped method of lectures and recitations on general hygienic subjects, which bored both her and the girls.

She finally shook herself out of her lethargy and got to thinking. As a result she decided to treat health subjects in the light of the needs of the girls in their probable future business and professional careers.

She collected forms used by business houses rating applicants for employment. Her cue was to have the first lesson on the importance of personal appearance in applying for and keeping a job. Here was a good chance to discuss the condition and care of hair, skin, teeth, eyes, posture, and dress, subjects which, enlarged upon, were broad enough to constitute the outline of work for the whole course.

In the work on the skin and its care, in addition to considering the kinds of baths and their uses, discussions were held on the various ways of cleansing the face, and relative advantages of soap and water and of creams, the sort of face powder to use and how to use it, and the correct kinds and uses of make-up. With regard to the hair, I showed in class various kinds of hair brushes and how to use them, and demonstrated the uses of hair tonics.

Toward the end of the course when the girls had acquired some background for judging, they became increasingly critical of advertising material seen in newspapers and magazines. At this

point, Miss Dee felt they were ready to go into community health problems under the subject "The Business Woman as a Citizen." She says, "a most interesting lesson led to a determination of what proportion of the average citizen's salary actually went to support community health agencies." This caused them to wonder what the citizen got in return for these expenditures. The logical thing then was to visit various community agencies, confer with department heads, read their literature, and have municipal and health department officials lecture to the girls. The interest and vital importance of these trips to the girls was shown by the fact that most of them voluntarily took time after school to make them.—M. Barbara Dee, *Health for the Business Woman, Hygeia* (Dec.), 1933, p. 1132.

A School Physician Writes the Editor of the Nursing Section—

His Letter—"Will you give me your opinion as to how much treatment and what kind of treatment may be rendered by the school nurse to school children? Is it the province of the school nurse to treat cases of impetigo and ring worm? How often may she dress contusions, abrasions, wounds, and infections, etc.? Is it permissible for her to use a therapeutic lamp in the treatment of certain injuries sustained by the athletes? How much responsibility, if any, beyond first aid must the nurse assume?"

The Reply—"I quote from the N.O.P.H.N. *Manual of Public Health Nursing*, Second Edition, Macmillan, New York, 1932, in the chapter on School Nursing Service (page 173):

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

"Treatments are given by the nurse only when she is working under a medical director or when a medical advisory committee has agreed upon standing orders." I fully agree with this.

If you have school nurses they should own Miss Chayer's *School Nursing*, G. P. Putnam's Sons, New York, 1931, which, on pages 46-48, treats of the school nurse and skin infections.

I have just been visiting the school health service in Evansville, Ind., which has a good medical director, Dr. C. C. Wilson, with six school nurses on his staff. Dr. Wilson gave me a copy of the *Standing Orders*, which his school nurses follow, a copy of which I am sending on to you. I know that Dr. Wilson works closely with the medical society in his community, and I feel that we can take his procedures and rules as models. You will note that Dr. Wilson's nurses make every attempt to urge home care of skin diseases by the family physicians, but he authorizes them to treat neglected cases at school. I feel that no school nurse should do this, however, without authorization by the chief medical inspector or a medical advisory committee from the local or county medical society.

In the *Manual of Public Health Nursing* (above referred to), on page 173, under "General Policies in Handling Emergencies" (referring to school nurses), the following statements are made, with which I agree:

"For injuries or accidents occurring in the home or out of school, responsibility rests primarily with the family physician."

"The nurse should not disturb a dressing put on by the family physician except at his request. She should not assume responsibility for the care of infections, but should impress on pupils, parents, and teachers the importance of a physician's care for such cases."

The first aid dressing is the only one the nurse should apply without definite orders from the family physician or school physician.

I think it is permissible for the school nurse to use a therapeutic lamp in the treatment of certain injuries sustained by athletes if she does it under the direction and supervision of a physician.

Of course, I think that first aid is a very minor part of a school nurse's duties. Her greatest value comes from her ability to teach, to be an interpreter of "medical, sanitary, and social procedures for the correction of defects, prevention of disease and the promotion of health." I am enclosing a copy of the *Objectives in Public Health Nursing*.^{*} Note under IV, those for the school age group. School nurses have a big task and should be well qualified for their work. I am enclosing the *Minimum Qualifications for Those Appointed to Positions in Public Health Nursing*.^{*} I don't know whether you have one school nurse or a supervising nurse and several staff nurses, but these standards ought to guide you as to what their qualifications should be before they are employed to do public health nursing in your schools.

NOTE: Since this letter was sent off, the matter of the therapeutic lamp mentioned was discussed with a school physician. His comment on the statement that the school nurse can use such a lamp if she does it under the direction and supervision of a physician was:

"The statement, as worded, undoubtedly takes care of the problem from the point of view of the school nurse. However, from the point of view of the school physician, I do not believe that he should assume such responsibility. His function is in the field of health protection and health education, and treatment of any sort, including that given by a therapeutic lamp, should be in the hands of the family physician or of some physician appointed to treat indigents."

^{*} Copies may be obtained from the National Organization for Public Health Nursing, 450 Seventh Avenue, New York, N. Y.

EDUCATION AND PUBLICITY*

Life Membership in A.P.H.A.—Twelve applications for life membership were presented for action at Indianapolis. Four of this number were from the Public Health Education Section. Also this section offered 7 applicants for Fellowship.

Usable Bibliographies on Child Health—We have mentioned the usability of the mimeographed reading lists issued by the Educational Service of the American Child Health Assn., 450 7th Ave., New York, N. Y.

A group of new issues and revised editions has been issued. *Single copies free.*

The lists illustrate how even very brief reading lists for teachers or for health workers may be made helpful and usable.

"The Administration of the School Health Program." 9 pages. "Some references which consider school health problems from the viewpoint of the school administrator." Includes: "General Policies and Principles," "Administering the School Health Program," "The School Health Program" (health service and health education).

"Health Education Bibliography: Junior and Senior High School." 5 pages. For administrators and instructors. "Helpful When Laying Plans," "Helpful When Subject Matter and Method are Being Considered," "Examples of Work Accomplished," "Of Special Interest to Teachers of Science," "Some Tests that Have Been Used to Evaluate Programs," "Useful When

Looking for Reference Material of Special Interest to the Pupils."

"Health Education in Elementary Schools." 5 pages. *References "selected to help the teacher to find guidance material, reliable and easily available. A series of searching questions with answers in the form of reading references.

"Some Recent Contributions to Health Education." 3 pages. For instructors giving courses in health education.

"Supplementary Reading Materials for Health Education." Grades I to IX. 6 pages. "Interesting types of reading suitable for classroom libraries."

Of Course We Want to Know Both Sides—Not often does governmental action arouse as much discussion in the business and advertising worlds as has the so-called "Tugwell Bill." Much of the discussion in the trade press is wild and far from the mark. But there has been much thoughtful and high-minded consideration of the bill.

There seem to be good reasons for believing that the bill should be modified, but in its present form it has rendered high service in helping leaders in the food, drug and cosmetic business to face realities from the public health point of view. The educational value of the bill in advance of Congressional action makes it worthy of mention in this department.

But public health workers who may explain or support the bill will not wish to overlook the questions raised by business men, many of whom very much want protection for their ethical businesses, as well as protection for the

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Elvert G. Routhahn, 139 East 22d St., New York, N. Y.

health of the public. Few of the references to the bill in public health journals suggest that both sides have been studied.

Look up recent issues of *Business Week* (New York) or any leading advertising journal, especially those for November and December. *Advertising and Selling*, 9 East 38th St., New York, N. Y., should be especially helpful. Note particularly articles in the Dec. 7, 1933, issue (15 cents), and the editorial, "Concerning Certain Misgivings About Food and Drug Enforcement."

Too Much Psychology?—Is it too much, because it is not enough, when we take selected emotions out of a box (or a book), pick the motivation buttons to press, and presto! we have changed or corrected, controlled or corralled the desired health habits!!

An author, discussing the writing of letters in *Printers' Ink Monthly* (185 Madison Ave., New York, N. Y. Dec., 1933, 25 cents), has some doubts about the ability of anyone who has acquired his psychology from a textbook, to put it to work:

"What do you think is wrong with these letters—or the people who wrote them, Leo?" I asked.

"I won't attempt to answer that one," he replied. "But here is the conclusion I've come to after studying a couple of hundred letters.

"Most of the letter-writers have apparently read the same books on psychology that I have. They also have been told that the first sentence or paragraph of a letter should be an attention arrester. So they start in psychoanalyzing—and if you don't think so just study carefully the letters you receive, particularly those designed to sell you something. You'll find that the writers of practically all of these letters have made a long-distance study of your inhibitions, complexes, fixations, or what have you. They have tried—oh, so hard and painstakingly—to adapt their letters to your nature. While they were trying to get you into a mental state in which you would be more willing to accept their proposition, they let their real message jell into a mess of hodge-podge."

"Well, you discovered something, didn't you, Leo? You found out for yourself that although it is often said that most anybody can write a good letter, very few do; that it wouldn't be so bad if letter-writers 'wrote as they talked,' but if they talked as they wrote, many of their listeners would think they had gone bugs."

Beginnings and Growth—Only recently have we looked up "Health Education" in *Encyclopedia of the Social Sciences*. This article by Dr. Iago Galdston devotes 8½ columns each 8½ inches long to the beginnings of health education and its development in recent years, to which is added a column of reading references. We believe that no other source will give so comprehensive and so readable a review. Surely all who are concerned with popular health education should read the article. Of course this seventh volume of the *Encyclopedia* is available in public and university libraries.

Several details are likely to cause some confusion. In naming national organizations there is lack of consistency in the use of the original or the present-day titles. The extensive and useful bibliography omits several significant references. Then it will be well to remember that a number of the activities and periodicals for which starting dates are given are no longer in existence.

"Hygeia," December, 1933—The editorial presents the a-b-c of "Amebic Dysentery," followed by:

"Holiday Follies"; "Let's Make Winter Sports Safer"; "Unpleasant Breath: A Symptom of Disease"; "Training for Athletics and Health"; "Waist-Lines and Life-Lines: Control of Obesity"; "Medical Notes from the Diary of Samuel Pepys"; "School Health Work on the Labrador"; "Before Baby is Two: Helping Baby to Learn"; "A Housewife Looks at the Committee on Foods"; "Exhibits at A Century of Progress"; "Feminine Beautification"; "What to Do for the Cross-eyed Child"; "Sex Education: The Period of Adolescence"; "A

Century of Progress in Medicine"; "Doorstep Babies" (the deserted ones); "After-Care of Infantile Paralysis"; "I Want to Know: What Happens When Your Heart Beats"; "School and Health," including "Boston's Contribution to Health Education"; "Teaching Health" (devices and methods); "New Health Books and Teacher's Materials"; "New Books on Health"; "Questions and Answers."

Slogans in All Languages—Can you get your slogan translated into all the languages spoken in your community, or your state?

You might make the translation job into a contest, giving awards for the most accurate and carefully written translations. Before the awards are announced you might give out the list of languages already represented, asking for other languages actually spoken in your community, or simply invite additions whether or not they are in use in your territory.

Legibility Makes Indexes Usable
—Small type, volume numeral in italic Roman, and article titles in all caps—these are features of the index of a health bulletin or house organ. Copy text on both pages of the index was short so that lack of space could not be the reason for the small type.

"In a City of Medium Size"—
"Social Hygiene Education," by Jean B. Pinney, is a review of one of the experimental campaigns conducted by the American Social Hygiene Association, with the coöperation of other agencies. This report of an educational campaign in Reading, Pa., "a city of medium size," tells of "Sponsorship for the campaign, financing, plans and objectives, campaign methods, newspaper coöperation, special coöperation with physicians, coöperation with civic and social groups, in the schools, industrial coöperation, training speakers, literature, films and exhibits, radio and checking campaign results."

The letter of invitation to sponsors is reproduced, as also the letter to employers having 50 or more employees, the educational folder, a wash-room placard, a talk announcement, and a letter to physicians. A page of newspaper clippings shows headline use of "gonorrhea" and "syphilis."

An effort was made to arrange a broadcasting program concerning the campaign, but the radio authorities, while regarding the talks which had been prepared as effective, felt it wise to decline for fear that some conservative listeners might complain to the State Radio Commission of the discussion of medical aspects of syphilis and gonorrhea.

In *Journal of Social Hygiene*, 450 7th Ave., New York, N. Y. Nov., 1933. 35 cents.

"Explain! Explain! Again Explain!"—Thus Sherwood Anderson writes to editor of *Today*, 152 West 42d St., New York (Dec. 2, 1933. 10 cents). "It is the thing needed. It must be done now, over and over, patiently and persistently."

Mr. Anderson is writing about social and economic problems. His plea might well be addressed to public health workers who need to "Explain! Explain! Again Explain!"

RADIO
We used to hiss speakers. Today we merely twist the dial.—*Atchison Globe*.

State and city departments and associations not mentioned below are invited to send copies of broadcasts as issued. With a view to increasing legibility the titles are written here as topics.

Baltimore City Health Department, Tuesdays, 6:00 p.m. over WBAB

Trichinosis; Baltimore's milk supply; Help control whooping cough; Safeguarding the drugs you take; Arthritis; Amebic dysentery; and "Mrs. Wells Learns About Tuberculosis" in which "Miss Truitt," a Health Department nurse, answers the questions of "Mrs.

Wells" (who is interested in a neighbor's daughter). *Copies free to health workers.*

Connecticut State Department of Health, Hartford:

Growth of children; Public health: Organized effort; Health in old age; Cost of venereal disease control (syphilis and gonorrhea are named); Some reasons for our behavior; Finding tuberculosis cases early; Seasonal growth of children; How clean is clean? *Copies free to health workers.*

Connecticut State Health Dept., Hartford, has announced broadcasts for every Thursday, 1:25 p.m., via WTIC, up to June 28, 1934. List of titles *free*.

Illinois State Department of Health, Springfield:

The drama and comedy of anesthesia at Century of Progress; A Century of humane care of the insane and nervous; Ninety years of Robert Koch at Century of Progress; A strange and new phase of modern medicine and biology; A century of progress in dental health; Progress in occupational therapy at the World's Fair; The use and abuse of Illinois streams by man; A health officer looks at milk at Century of Progress; Insomnia and public health; Health value of communications exhibits at Century of Progress; A century of progress in hospitalization; Two centuries of Joseph Priestly and his discovery of oxygen. *Copies free to health workers.*

The Century of Progress broadcasts from Illinois are likely to contain usable material which need not tie up with the World's Fair.

MAGAZINE ARTICLES

"Don't Drop Your Guard." Page editorial in *Colliers Weekly*. Dec. 2, 1933. "Germs know no social barriers nor are they interested in bank accounts." An especially timely and constructive statement with more than 2,000,000 circulation.

"Eyestrain: What It Is and How to Avoid It," by Margaret Schaefer. *American Federationist*, Washington, D. C. Nov., 1933, 20 cents.

"Heroes of Health," a series of three articles, describe "heroism of workers in the U. S. Public Health Service." By a staff writer of N. E. A., that is, News-

paper Enterprise Association, serving Scripps-Howard and other newspapers.

"Ready for Winter?" by Dr. Walter R. Ramsey. *Farmers Wife*, St. Paul, Minn. Nov., 1933. *Sample free*. This is one of the articles on child care which appear monthly with more than a million circulation. Possibly you have met one of the editors, Carroll P. Streeter, at A.P.H.A. Annual Meetings.

"Should the States Control Medical Care?" A debate prepared by Prof. Walter B. Emery. *Scholastic*, Chamber of Commerce Bldg., Pittsburgh, Pa. Nov. 25, 1933. Introductory review of the question: "Affirmative Brief" ("I. There is need for a change in our present system of private medical practice"; "II. The proposed plan would remedy the evils of the present system."); "Negative Brief" ("There is no need for the proposed change of the Affirmative"; "II. The proposed plan is undesirable"; "The proposed plan would give rise to other evils"); "References" (General; Affirmative; Negative). Copy for 10 cents.

To be announced in bulletins or house organs, posted on bulletin boards, and otherwise brought to the attention of new readers.

"America's Contribution to Leprosy Control," by L. E. Danner. *Literary Digest*. Nov. 4, 1933.

"Common Colds," by J. A. Tobey. *American Mercury*. Nov., 1933.

"Euthanasia Considered," by H. E. Barnes. *New York World-Telegram*. Oct. 27, 1933. "It would put an end to a vast volume of unnecessary human suffering."

"Patent Medicines and the Law," by A. J. Cramp. *American Mercury*. Nov., 1933.

"She Couldn't Change a Tire. But—," by Willard Price. *Rotarian*, 211 West Wacker Drive, Chicago, Ill. Nov., 1933. 25 cents. The working day of a rural nurse and the results of a county health survey.

HOUSE ORGANS

Doubtless all of our Canadian readers are familiar with *Bulletin* of the Canadian Tuberculosis Assn., Plaza Bldg., Ottawa, Ont.

Ke Ola O Hawaii, P. O. Box 39, Honolulu, T. H., is published by the Tuberculosis Assn. of Hawaii.

Non-residents, 24, residents, 29, a total of 53, the automobile death toll of New Haven in both 1931 and 1932, was exceeded by 11 in 1929. So reports *Health*, New Haven Dept. of Health on its cover page.

"Timely Tips on Scout Protection," by F. C. Mills. *Scouting*, 2 Park Ave., New York. Dec., 1933. 10 cents. "Orders or Instructions—Which?" The futility of "arbitrary protection" without "educational follow-up."

The July-Sept., 1933, issue of *The Commonwealth*, Massachusetts Dept. of Health, is an example of the one-subject house organ. "Epidemiology" is the subject.

"The Public Milk Supply and the Public Health," by Dr. M. E. Barnes. This occupies all of the July-Sept., 1933, issue of *Iowa Public Health*, Des Moines, Ia.

"Health Education Program of the W. K. Kellogg Foundation," by Lulu St. Clair. *Michigan Nurse*, Lansing, Mich. Nov., 1933. 20 cents.

"Mark Time" is New Jersey's talking character who discusses in homely, realistic fashion the practical workings of public health laws and regulations. In *Public Health News*, State Dept. of Health, Trenton.

"Inspector Brown" is one of the chatty individuals who discusses public health problems with the "Health Officer" in *Jamaica Public Health*, Central Board of Health, Kingston. In Nov., 1933, Inspector Brown reports on opposition to wrapped bread:

One bakery manager says: "that if the bread is wrapped at the bakery immediately after it is baked, the baker's assistant places

it on the rack to cool, then later it is passed out to the delivery man who places it in his wagon, then it is taken to the shop where it is handled at least two more times on being placed on the shopkeeper's shelves; when all this is done and the shopkeeper delivers it to the homes, the paper in which the bread is wrapped will have become so dirty that the lady of the house will refuse to have it."

CONTESTS

Ohio newspaper women, meeting in annual convention in October, awarded prizes for "the best collection of Christmas health seal sale stories in a paper of less than 25,000 circulation," and for the same in a paper of more than 25,000 circulation.

Winners in the radio sketch contest are announced in *Public Health Nursing*, 450 7th Ave., New York, N. Y. Dec., 1933. The winning sketch, "Inspiration," by Mary R. Young, is published in full.

The Ohio Public Health Assn. is repeating its awards for Christmas seal editorials. \$50 for the best editorial in a daily paper; \$50 for the best in a weekly; \$25 for the 2nd best.

Prizes are offered for descriptions or models of "improvised equipment made from materials obtainable in or by the average home, for use in home nursing care, demonstrations, health education in home, school, industry or clinic. . . . We are particularly eager to see health education material included in this contest."

Contest closes Feb. 20, 1934. See full particulars in *Public Health Nursing*, 450-7th Ave., New York. Nov., 1933. 25 cents.

NEW

Canadian Health, Canadian Social Hygiene Council, 105 Bond St., Toronto, Ont. "Devoted to the promotion of personal and community health." Quarterly. 50 cents per year. Sample free.

HONORABLE MENTION

To New York State Department of Health: for an annual report with both "contents" and "index," and for a chapter reporting "Public Health Education."

DEPRESSION

Almost a depression issue is the Oct., 1933, number of *Quarterly Bulletin*, Milbank Memorial Fund, 40 Wall St., New York, N. Y. The contents include: "Health and the Depression," by Edgar Sydenstricker; "Sickness and the Depression," by Perrott and Collins; "Nutrition and the Depression," by Kiser and Stix; "Diets of Low-Income Families in New York City," by D. G. Wiehl.

"Crisis in the Hospitals," by Mary Ross. *Survey Graphic*. July, 1933. 30 cents. "In private hospitals, empty beds, . . . In public hospitals, beds in the aisles . . . Ways out."

"Dollars and Lives," by C.-E. A. Winslow. *Survey Graphic*, 112 East 19th St., New York. Aug., 1933. 30 cents. "The drive to cut public-health budgets . . . parsimony and sometimes medical politics lie behind . . ."

"Health and the Tax Dollar." *Public Health*, Dept. of Health, Newark, N. J. Sept., 1933. An appeal based on findings of A.P.H.A.

"The War on Depression," by Glenn Frank. *Bulletin*, American Hospital Assn., Chicago, Ill. Oct., 1933. Includes "The Heroism of the Hospitals." "Somewhere the problem of bringing medical service into a rational relation to the buying power of the rank and file of Americans will have to be solved." A limited number of free copies.

"School Lunches Prove Their Value," a group of three papers. *Journal of Home Economics*, 101 East 20th St., Baltimore, Md. Nov., 1933. 30 cents. Partly depression values—and more.

"How to Cook Salt Pork," a broadside prepared by Bureau of Home Economics, Dept. of Agriculture, Washington, D. C., copies of which are to be supplied to families receiving salt pork through relief agencies.

HEALTH EDUCATION

The following references appeared in recent issues of *Library Index*, National Health Council, 450 7th Ave., New York (sample free):

"The Importance of Health Education," by W. M. Lloyd, M.B., D.P.H. *Medical Officer* (London). 50:142-43, Sept. 30, 1933.

"The Teaching of Social Hygiene in Schools by Means of the Film," by Lucien Viborel. *International Review of Educational Cinematography* (Rome). 5:596-99, Sept., 1933.

"The High School Health Council in Action," by E. H. Hastings, Jr. *Journal of Health and Physical Education* (Ann Arbor, Mich.). 4:3-6, 55, Oct., 1933.

"Unit Teaching in Health Education in the Secondary Schools," by J. V. Latimer. *Journal of Health and Physical Education* (Ann Arbor, Mich.). 4:10-12, 56, Oct., 1933.

"School Lunches Prove Their Value." *Journal of Home Economics* (Baltimore). 25:755-62, Nov., 1933. "Correlating Class Activities and Community Needs with the School Lunch," by L. A. Williams; "A School Coöperative Cafeteria," by M. B. Stover; "The First Penny Lunch," by Albertina Bechmann.

"Teaching Health in School Cafeterias." Baltimore's poster program. *Trained Nurse and Hospital Review* (New York City). 91:334-36, Oct., 1933.

"Public Health Education," by D.

V. Curry, M.D. *Health Officers' World* (Milwaukee, Wis.). 1:6-7, July-Oct., 1933.

"Administrative Methods in Health Education," by A. M. Kerr, M.D. *Journal of Health and Physical Education* (Ann Arbor, Mich.). 4:14-16, 59-60, Nov., 1933.

EDUCATIONAL AND REFERENCE

Under this heading we hope to mention new publications and new lists of publications and other available materials useful in health education, free or for a named price, throughout either or both the United States and Canada. Not all of the national agencies send in their new material.

Material from commercial sources is listed for your information.

When reprints are sent please state if copies will be supplied free or for a specified cost. This information about all publications is desired so that extra correspondence by interested people may be avoided.

Comment, for or against any materials, is most welcome, either for publication or for the confidential use of the editor of this department.

"Just Suppose . . ." is a small 12-page booklet issued by the Cancer Control Committee, Dept. of Health, New Haven, Conn. The cover is one of the best. From the bottom of the page arise in solid dark green the ragged mountain peaks representing New Haven's cancer death rate for 20 years. The title appears in white letters across the solid green. The rough finish paper and leaded type give a readable appearance to the inside pages.

"Cancer Control" is an inexpensive looking sheet, printed on one side, with a "Cancer Can Be Cured" statement in a box near the top. Most of the space is filled with case records headed, "Cancer of Cheek," "Cancer of Lips," etc. Each case is presented concisely

under "History," "Examination," "Treatment," "Result," "Operation," "Result." Probably used with a carefully selected audience. Also issued by Cancer Control Committee of New Haven Dept. of Health.

New York State Dept. of Health, Albany, has reproduced two Children's Bureau folders. "Sunlight for Babies" was multigraphed, and "Minimum Standards of Prenatal Care" was multi-lithed. The second is the new offset adaptation of the multigraph. Readers of the folders would not distinguish the type from printing. These folders illustrate a good grade of publication produced without benefit of the public printer.

"Smallpox and diphtheria—Both Can Be Prevented." Distributed by City Health Dept., Baltimore, Md. The control of smallpox used to illustrate practicability of diphtheria control.

"A List of References on the Care of the Mother Before the Baby Comes—And Afterwards," and "Child Health References for Parents." Reprint from *Child Health Bulletin*, Sept. and Nov., 1933. 4 pages. *Single copies free.* American Child Health Association, 450 7th Ave., New York, N. Y.

"Cleansing and Disinfection." New York State Dept. of Health, Albany. 7 pages.

State Charities Aid Assn., 105 East 22d St., New York (3 cents each):

"Up to Now," by Homer Folks. Health progress in New York. 9 pages.

"For the Next Decade," by Dr. James Alexander Miller. Control of tuberculosis.

"The Contributions of Health Insurance to the Tuberculosis Movement in England," by Dr. G. F. McCleary, British Ministry of Health. 4 pages.

"Common Interests between the Control of Tuberculosis and Syphilis," by Dr. Thomas Parran, Jr. 4 pages.

"The State's Interest in the Control of Tuberculosis," by Governor H. H. Lehman. 6 pages.

BOOKS AND REPORTS

Pathogenic Microorganisms — A Practical Manual for Students, Physicians and Health Officers—By William H. Park, M.D., and Anna W. Williams, M.D. (10th ed. rev.) Philadelphia: Lea and Febiger, 1933. 867 pp. Price, \$7.00.

A book which has reached its 10th edition has won its place in public esteem. There is no question that this work has been well received everywhere and stands today as one of the very best which can be given to students in medical schools. In the 10th edition numerous additions have been made, such as are necessary in a rapidly advancing science like microbiology. Indeed, the new methods and discoveries come with a rapidity that is almost bewildering.

This edition has full accounts of active immunization against diphtheria and scarlet fever. More of these immunizations have been done among the school children in New York than in any other part of the world, and we naturally turn to New York for information on the subject. Therefore, it seems unfortunate that the book is not up to date concerning one of the most important advances along this line which have been made. We refer to the alum precipitated toxoid, for which in this country we are indebted chiefly to the studies of the late Dr. Leon C. Havens, of the State Board of Health of Alabama, described in this *Journal*, June, 1932. A single dose only is required, and reports from various sources indicate that it is preferable to the two dose method heretofore largely practised. From the standpoint of administration, it certainly has great advantages over two or more doses. The

authors also cling to the "antigenic unit" obtained by flocculation, though the National Institute of Health does not recognize this as official, and prefers the animal test.

A number of changes have also been made in the chapters on Pyogenic Cocci and Pneumococci, though it is too much to say that this puzzling group of organisms has been made entirely clear.

The authors still persist in using "B.C.G." to describe Calmette's vaccine. The initials come from Bacille Calmette-Guérin, and Calmette has always used BCG. Certainly the punctuation given cannot be justified in view of its derivation.

There are too many misprints, most of which are not confusing, but some which may mislead a student. On page 512, "antiformin" is spoken of as an "alkaline hydrochloride solution," though elsewhere it is correctly given.

The book is also not up to date on some nomenclature. In the 8th edition there was a rearrangement of the grouping of organisms to conform more closely to the classification adopted by the Society of American Bacteriologists. This has been adhered to, but the most recent nomenclature has not been employed in all cases. On page 457, the dysentery group is classed under Genus *Eberthella*, whereas *Shigella* has now supplanted the older term.

The statement that "we believe" the credit for isolating the first bovine bacillus from a child belongs to Ravenel is still maintained. The correct statement is that Ravenel was the first to isolate the bovine bacillus from a child and prove its pathogenicity by inoculation of cattle, according to the method suggested by Koch. In other words, it

was the first scientific proof ever given of the danger of bovine tuberculosis to human beings, though many had believed in it and adduced clinical evidence of such infection. There does not seem to be any reason for the authors saying "we believe," etc. The literature is open to them and the matter is easily proved one way or the other.

Apart from the errors mentioned, the book is admirably printed and made up, and the illustrations good and sufficient. It can be recommended without hesitation for student use.

MAZÛCK P. RAVENEL

The Science of Radiology—Edited by Otto Glasser. Springfield, Ill.: Thomas, 1933. Price, \$6.00.

This book, edited by Otto Glasser, is a product of 26 contributors, all well known in the field of radiology. It begins with a history of Röntgen and his discovery; next the story of Pierre and Marie Curie, and then a chapter on American Pioneers in Radiology. The following chapters consider the progress of science, physics, general apparatus, tubes, screens, dosage, etc., after which come the diagnostic features and therapy. Radium is considered in practically the same order.

A chapter is devoted to the biological effects of X-ray and radium, and another chapter to the nature of Cosmic rays and the Gurwitsch rays. Although each chapter is complete in itself, there is appended a list of references which add to their value. The early chapters on the history and biological effects would alone make the book worth while. The chapter on Industrial Radiology is very interesting for those in this field of work. Another chapter is on Radiologic Societies and Literature, in which all workers will find much of interest and value.

All those who are interested in X-ray or radium from the scientific as well as

the practical standpoints will find this book of the utmost value, covering, as it does, these subjects in an interesting and practical way. Indeed, there is no other book that we know of which covers the field as this does. The names of the contributors vouch for the scientific character of the articles, in addition to which, it is vouched for by the American Congress of Radiology, which chose the members of the Executive Council who have been particularly interested with Dr. Byron H. Jackson, Chairman of the Committee on History and Education, in the production of this book.

It is impossible to speak too highly of the printing and make-up of the book. It might well be called a deluxe edition, and if the reputation of Charles C. Thomas were not already so well established, this book alone would give him a high place. The illustrations are abundant and excellent.

DUDLEY A. ROBNETT

Iowa White House Conference on Child Health and Protection—Planning Commission, Iowa White House Conference, Des Moines, Iowa, 1932. 506 pp. Price, \$1.95.

This is a very comprehensive report of the proceedings of the Iowa White House Conference on Child Health and Protection, Des Moines, Iowa, April 14 and 15, 1932.

The volume should be of value not only to those interested in a study of child welfare, but especially to Iowa citizens who wish to know what is going on in their state in the interests of children.

The report, which is accurate and authentic, is divided into 4 sections: Medical Service; Public Health Service and Administration; Education and Training; The Handicapped.

At the end of each report there is an interesting summary or conclusion. The reviewer cannot begin to enumerate

the interesting conclusions reached in the various fields of child welfare endeavor as carried on in Iowa. The volume must be read to secure this information. ELDRED V. THIEHOFF

Maternal Mortality in New York City—By the *New York Academy of Medicine Committee on Public Health Relations*. New York: Commonwealth Fund, 1933. 312 pp. Price, \$2.00.

There have been during the last few years a number of studies of maternal and infant mortality. These inquiries have more often been carried out as part of health department programs or under legislative mandate. The investigation under review, on the contrary, was carried out by the medical profession itself and this is as it should be. Only an organized group of medical men can evaluate properly the medical factors in the maternal mortality and, more important still, make the necessary criticism of medical practice.

The piece of work under discussion deals with maternal deaths in New York City, being a study of all puerperal deaths in that city during the years 1930 to 1932, classification of the facts discovered and drawing conclusions therefrom. These objectives have been pursued, apparently, with much care and intelligence as might have been expected from the group sponsoring and executing the study.

In a brief review one can only indicate some of the important points of the book with a view to interesting the reader to dip into the volume itself. In the first place, there is a statement of the problem and here we find the assertion made that the figures "show no decrease in the puerperal death rate over a period of 10 years in the country, the state, or the city of New York." This statement, to my way of thinking, has to be borne in mind always in read-

ing the report since it supplies a touchstone to apply to both the data and the conclusions.

From the point of view of the public health worker, chapter 3, dealing with preventability of death, shares the center of interest with chapter 9—conclusions and recommendations. Other chapters deal with puerperal and extra-
puerperal causes of death; various factors affecting puerperal mortality; hospital practice; attendant at delivery; and midwife practice. At the end of the book are the tables upon which the whole is built.

In judging the preventability of death, the committee has used as its criterion "the best possible skill, both in diagnosis and treatment, which the community could make available." This is a flexible standard, as worded, and rightly so. A preventable death in New York City may be a non-preventable death in Plum Hollow, 50 miles from a specialist in obstetrics. On the above basis, the committee estimates that 65.8 per cent of the deaths they studied in New York City were preventable. (It is interesting to compare this figure with that of 39 per cent which was the estimate of a special legislative commission studying maternal deaths in Massachusetts in 1920.) Then, the New York committee tries to allocate the blame for the preventable deaths and charges the medical man with 61.1 per cent, the patient with 36.7 per cent, and the midwife with 2.2 per cent. As for factors entering into this rate, we find overuse of anesthesia, operative delivery, cesarian section, and hospital delivery. The midwife comes in for a word of praise; the committee feels that she has her place in obstetrical practice.

Another angle of this report which should be touched on here is that of the prenatal care these puerperal cases had received. Of a total of 1,538 women dying of puerperal causes ex-

clusive of abortion and ectopic gestation, a little more than 39 per cent are said to have had adequate prenatal care. (Incidentally these seems to be a discrepancy between Table 71 on page 167 and that on page 229 due to the exclusion of 26 cases.) Again compare these figures with those of another Massachusetts study (1922 and 1923) where only 11 per cent were found to have had adequate prenatal care.

If space permitted, it would be interesting to discuss the conclusions and recommendations of the committee, but every student of maternal mortality should read them for himself. They touch on such familiar subjects as lay ignorance and misinformation; failure of the attendant to give proper care; too ready operative interference, especially cesarian section; inadequate hospital standards; insufficiently trained midwives. The recommendations naturally have to do with the correction of the above mentioned weaknesses in medical practice. The report closes with the statement: "The hazards of childbirth in New York City are greater than they need be. Responsibility for reducing them rests with the medical profession."

This is a most timely and valuable study. Yet even after an investigation as thorough as this, one is left with the feeling that much of maternal mortality is still unexplained. Here is our largest city, with the best available in medical, nursing, and hospital care; with licensed midwives; with systematic effort constantly being made to inform the public; yet the maternal mortality for the city—as established by this survey—was 5.98 in 1932 as compared with 5.33 in 1920 (the latter according to the official figures); practically no change in 12 years. Furthermore, more than 39 per cent of those who died from puerperal causes are said to have had adequate prenatal care. Many

rural communities with a fraction of these facilities for treatment and with little prenatal care given can show as good or better rates. I find it hard to believe that "meddlesome midwifery" is the whole answer, since that factor is not confined to the city. There seem to be a factor or factors not yet fully appreciated. Might one suggest to the committee that an additional study of a series of pregnancies which did *not* result in death might throw light on the puzzle. MERRILL E. CHAMPION

The Great Doctors. A Biographical History of Medicine—By Henry E. Sigerist. New York: Norton, 1933. 436 pp. Price, \$4.00.

The first edition of this book was written in Germany in 1933. Since coming to America, a chapter entitled "William Osler" has been added. This is evidently a peg on which to hang a very sketchy and imperfect account of American medicine, and to praise the medical faculty of Johns Hopkins University of which the author is now a member. This chapter begins: "The New World, America, entered the medical stage!" When did this occur, and what did Dr. Osler have to do with it, since it goes back to 1677? He mentions the names and accomplishments of several men who have been prominent in American Medicine, like McDowell, Beaumont, Marion Sims, Drake, and Oliver Wendell Holmes.

The book contains too many half-truths to be regarded as a reliable history. It is well known that when the medical faculty of Johns Hopkins University was organized in 1893, four of its members were graduates of the University of Michigan, and two were on its faculty; yet the University of Michigan is not even mentioned, though many believe that it was in the Medical School there, under Victor C. Vaughan, that the great reform in medical teaching in the United States

began. Welsh is spoken of as a pupil of Ludwig and Cohnheim; Mall worked with His and Ludwig; Abel was a pupil of Schmiedeberg, though Welsh got his beginning in this country, and Mall and Abel were both graduates of the University of Michigan, from which they evidently derived their initial inspiration. What reason have we to think that studying under German professors, on which stress is laid, not only for those mentioned but in regard to others, was what made them great?

Among other half-truths is the claim, without discussion, that Nicolaier discovered the tetanus bacillus and Fränkel the pneumococcus. We know that Nicolaier produced tetanus by inoculation of garden earth, but if he saw the bacillus, he did not give a description of it by which it is recognizable at present. He described in the lesions, cocci and a number of bacilli. Rosenbach, in 1886, was the first to describe the drumstick forms which are so characteristic, and in the same year, Flügge described terminal oval spores. It was isolated in pure culture first by Kitasato in 1889. In regard to the pneumococcus, it is well established that it was seen by Pasteur and by Sternberg, both in the same year. The work which established its relation to pneumonia was carried out by a number of men, among whom Fränkel was one. The type of reasoning adopted by the author would attribute the discovery of the diphtheria bacillus to Klebs, who undoubtedly saw it in the membrane and described it before Loeffler grew it, and the discovery of the pneumococcus to Pasteur and Sternberg.

Another half-truth, if indeed it is at all true, lies in ascribing the discovery of ether as an anesthetic to Morton, who is said to have been the first to induce ether anesthesia. It has been proved repeatedly that the credit is due to Dr. Long, of Georgia. The author might well have consulted his col-

league, Dr. Welsh and Dr. Young, on this point. It is true that there is a controversy over it, but the dates show clearly priority for Long, though publicity was due to Morton. The witty reply of Oliver Wendell Holmes, when asked to whom credit should be given, "To e(i)ther," may be recalled.

An author certainly has the right to pick his subjects. Professor Sigerist recognizes that he has left out many worthy men, but as he states particularly that the book is written for the practising physician and his labors, we feel that we have a right to criticise the omission of Louis, who first introduced the Numerical Method, and who revolutionized the teaching of medicine as well as the study of cases. Dr. Osler is our authority for this statement, though we believe that it is universally acknowledged. In this connection, we wonder if Professor Sigerist has read *Some Aspects of American Medical Bibliography*, by William Osler (1902). This gives a much better idea of medicine in America than what he has said, though it makes no pretense of being a complete history.

The book starts with Imhotep and Aesculapius and carries us on down through the centuries, giving a brief account of many of the well known surgeons, physicians, and laboratory men to whom we owe so much.

The illustrations are numerous and excellent. The printing and binding are also excellent, though there are some errors, such as Nikolaier in the text and Nikolaer in the index.

In spite of mistakes in diction which will mislead the "non-expert" such as saying that Pasteur found a "remedy" for hydrophobia, and the half-truths which we have pointed out, the book can be heartily recommended for those who wish to know something about the great doctors included.

MAZÛCK P. RAVENEL

The Joy of Living. An Autobiography—Dr. Franklin H. Martin. *New York: Doubleday, 1933.* Vol. I, 491 pp. Vol. II, 526 pp. Price, \$7.00.

The story of the life of a distinguished physician who has lived in the interesting age of modern medicine, who has seen swept aside the false beliefs that have dominated sanitary science for so many centuries and who has contributed so generously, himself, to medical progress. Endowed with the rugged qualities and thrift of Dutch and Canadian grandparents, the author grew up during those stern and vigorous pioneer days in Wisconsin and Minnesota.

Accustomed to work from early boyhood, his advent into the field of medicine seemed quite by accident, but, once arrived, he soon became interested in the social and communal aspects of his profession and gave generously to

the advancement of educational and administrative services.

Through the publication of *Surgery, Gynecology and Obstetrics* and the creation of the "Clinical Congress of Surgeons" and the "American College of Surgeons," Dr. Martin has provided distinct contributions to the advancement of postgraduate teaching.

He played a prominent part in directing the medical and public health services of the military and civil populations of our country during the World War.

His autobiography will provide not only refreshing reading for those who seek relaxation in a life story well-told, but will serve the physician and public health worker as a valuable guide and reference book in the development of the sanitary science services, both scientific and administrative.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY
WITH ANNOTATIONS

Early Care of Defective Teeth—Coining the descriptive term "dental cripples," this article is a plea to the pediatrician (and the nurse should be included) to watch for defective dentures and to get the cripples early under the care of orthodontists.

BONIN, C. P. What the Pediatrician Can Do for Dental Cripples. *New Eng. J. Med.* 209, 18:875 (Nov. 2), 1933.

Amebic Dysentery—Information is given about amebic dysentery, the Chicago outbreak, and what has been done to control the spread of infection, all of which will be useful in answering the questions that popular interest is likely to arouse.

BUNDESEN, H. N., *et al.* The Health Hazard of Amebic Dysentery. *J.A.M.A.* 101, 21:1636 (Nov. 18), 1933.

Collateral Values of the Health Examination—How the health examination, if adequately followed up, may become the agency for establishing a continuing close relationship between the patient and his family doctor is the point of this discussion of examination methods.

CRAMPTON, C. W. The Health Examination, Life Service, and the Family Doctor. *New York State J. Med.* 33, 20:1216 (Oct. 15), 1933.

Sun Spots and Weather—Though sun spot cycles cause solar changes in sufficiently pronounced to affect human affairs appreciably, they are sometimes great enough to appear extensively in the growth of trees, so we learn from an exceedingly detailed research.

DOUGLAS, A. E. Tree Growth and Climatic Changes. *Sci. Month.* Dec., 1933, p. 481.

How We Catch Colds—Just when we are comfortably assured by convincing studies that people may con-

veniently be grouped in relation to the number of colds they enjoy per annum, along comes this research which shows by mathematical computations, much too involved for this particular brain to follow, that catching cold is a mere matter of chance. Further, one may conclude that stability of resistance to colds is not characteristic if the sample populations studied are representative.

GAPAFER, W. M. and DOULL, J. A. Stability of Resistance to the Common Cold. *Am. J. Hyg.* 18, 3:712 (Nov.), 1933.

How Dangerous Is Unwrapped Bread?—In this series of papers the sanitary aspects of wrapping bread before delivery are thoroughly aired. One discussant had the temerity to suggest that those who were so concerned by the grave health menace of unwrapped bread seemed to forget the greater menace of contamination from unwrapped salads, fruit and vegetables eaten raw, but his remarks were scornfully ignored by the viewers-with-alarm.

LAMPIT, L. H., *et al.* The Relation of Wrapping Papers to Food, Etc. *J. Roy. San. Inst.* 54, 5:239 (Nov.), 1933.

Supervising British Midwives—One quotation is sufficient to indicate the practical level of this discussion of the increasing importance of the British midwife who delivers 3 to 4 out of every 5 women, and who is held by some British obstetricians to be the proper person to undertake the normal case. Here is the quotation: "It is true that sometimes the objection of the patient and her relatives to the prospect of a retinue of inspectors, health visitors and supervisors has to be overcome, and possibly the midwife herself may wish to avoid the possibility of earning the handicapping reputation of being 'fussy.'" Seldom does one see such

practical common sense seep into our American dissertations.

MACLEAN, E. The Rôle of the Midwife in National Maternity Service. *J. State Med.* 41, 11:643 (Nov.), 1933.

Studies on Encephalitis—Virus of encephalitis (St. Louis outbreak) was carried successfully through five passages in rhesus monkeys but could not be transferred successfully through mice, rabbits, or cebus monkeys, indicating that *herpes* virus did not play an etiological rôle in the St. Louis epidemic.

MUCKENFUSS, R. S., *et al.* Encephalitis: Studies on Experimental Transmission. *Pub. Health Rep.* 48, 44:1341 (Nov. 3), 1933.

Experience With BCG—These are important findings: "BCG is so attenuated that even under the most favorable conditions of artificial cultivation it is difficult to increase its virulence to any degree. . . . We do not think that the slight primary tuberculous infection . . . produced by vaccination diminishes resistance. . . . Children of tuberculous families vaccinated orally with BCG show lower mortality from tuberculosis than corresponding controls. . . . The allergy produced by BCG apparently does not usually last for more than two or three years."

PARK, W. H., *et al.* Effect of Vaccination With BCG on Children from Tuberculous Families. *J.A.M.A.* 101, 21:1619 (Nov. 18), 1933.

Persuading Venereal Patients—In a city of more than 100,000 population a social hygiene educational campaign of a month's duration was carried out to determine its effect on medical treatment. Physicians reported 58 more new cases (an 80 per cent increase) than the previous month directly attributable to the campaign; other less tangible benefits are also claimed.

PINNEY, J. B. Social Hygiene Education

in a City of Medium Size. *J. Social Hyg.* 19, 8:415 (Nov.), 1933.

Tuberculosis Among Italians and Jews—A study of 373 Italian and Jewish families registered with the Phipps Institute leads to the conclusion that the type of infection differed in the two races. Among the Italians the disease attacked a younger group and was more quickly fatal than among the Jews. Jewish morbidity rates were higher than Italian but mortality rates were lower.

PUTNAM, P. *The Bionomics of Families Attending a Tuberculosis Dispensary.* *Am. Rev. Tuberc.* 28, 5:537 (Nov.), 1933.

Aluminum's Non-Existent Dangers—We thought the last gun had been fired in the battle about the supposed dangers of aluminum, but here is another research which concludes that aluminum is not cumulative in the tissues and no harmful results may be expected from soluble aluminum occurring in foods or introduced by utensils.

SCHWARTZ, E. W., *et al.* The Extent of the Retention of Ingested Aluminum. *J.A.M.A.* 101, 22:1722 (Nov. 25), 1933.

Gloomy Gonorrhea Statistics—From a survey of 16 communities in 1927, it was estimated that there were 474,000 cases of gonorrhea constantly under treatment in the United States. Three years later a resurvey indicated a decrease of 10–20 thousand cases, but the decrease is due to the failure of infected persons to seek medical treatment. It has been estimated that there are 679,000 fresh gonorrheal infections each year.

USLITON, L. J. Trend of Cases of Gonorrhea Under Treatment or Observation in the United States. *New Eng. J. Med.* 209, 20:996 (Nov. 16), 1933.

Why Eskimos Are Diphtheria Immune—Finding Eskimos immune to diphtheria, though with no evidence of

having ever been infected, led to the assumption of the "maturation immunity" theory. In the latest study here reported *C. diphtheriae* were found to be present in the throat flora of the Eskimos. This warrants the belief that carriers do exist, and that the immunity discovered is specific. Thus the original "maturation" theory is invalidated.

WELLS, J. R. The Origin of Immunity to Diphtheria in Central and Polar Eskimos. *Am. J. Hyg.* 18, 3:629 (Nov.), 1933.

Rural Prosperity and Health—Despite the fact that other studies show high mortality associated with low economic status, this exceedingly thorough and inclusive statistical analysis of cer-

tain rural groups finds that when indices of urbanization are held constant, the correlation between prosperity and mortality disappears. A fine example of what may be done with our largely neglected gold mines of statistics.

WU, C. K., and WENSLow, C.-E. A. Mortality, Prosperity and Urbanization in United States Counties. *Am. J. Hyg.* 18, 3:37 (Nov.), 1933.

Newer Milks for Babies—Vitamin D milk's advantages in infant feeding are that it is the most palatable form of administering the antirachitic factor; its disadvantage is that it costs more than milk plus cod liver oil.

WYMAN, E. T. Vitamin D Milk. *New Eng. J. Med.* 209, 18:889 (Nov. 2), 1933.

NEWS FROM THE FIELD

Southern Medical Association Resolutions

AT the recent meeting of the Southern Medical Association held in Richmond, the following resolutions were passed:

WHEREAS, investigations reveal information that nutritional deficiency is constantly assuming a more important rôle as the etiological factor of many diseases that have heretofore not been understood, and it is now known that there are present in the United States a great many diseases belonging to this group, some of which diseases are widespread, increasing in number, and are seriously undermining the health and vitality of the people of this country, and,

WHEREAS, we have little definite knowledge of the chemistry of our foods, because analyses which have been made in order to determine their nutritional value have been local or sectional and no sustained effort has been made upon a broad scale to supply such information as is necessary in order to determine the localities from which our food supply should be drawn, and,

WHEREAS, it is known that in certain localities and under certain circumstances, the

chemical elements of common foods, such as milk, fruits, vegetables, and cereals, show marked differences in value, while it is known that in other localities, certain vegetables absorb poisonous substances which render them of doubtful food value, and,

WHEREAS, no real progress can be made in the solution of nutritional deficiency diseases until chemical analyses of foods are made upon a broad and impartial scale and the relationships of the different chemical elements studied with scientific care, and

WHEREAS, the whole scientific world is aroused to the importance of this fundamental work in order that grave public health problems and the vitality and strength of the people of this nation be safeguarded; therefore be it,

RESOLVED, that the Federal authorities be urged to undertake this work upon a broad, comprehensive, and impartial scale in collaboration with selected medical colleges in the different sections of the country.

RESOLVED (2) that the Southern Medical Association urge that this work be undertaken at the earliest possible moment.

RESOLVED (3) that this association request the

coöperation of all other state and national medical associations in this country.

RESOLVED (4) that the Southern Medical Association appoint a committee whose purpose it shall be to confer with the national authorities at the earliest possible moment and urge them to proceed with the work.

There can be no question of the importance of this matter. Studies for the past 10 years have all pointed in the direction of the importance of proper nutrition, and our recent discoveries have shown scientifically the reasons. Many private laboratories are at work, and our government is at present paying attention to the subject in several divisions, but there is still need for extensive studies on the basis laid down in the resolutions.

DEATH OF ALFRED F. HESS

DR. Alfred Fabian Hess of New York City, well known pediatrician and research worker and a Fellow of the A.P.H.A., died suddenly of heart disease on December 5, 1933, at the age of 58. Dr. Hess was a pioneer investigator of scurvy and rickets and published noteworthy books on these subjects, and he also made important studies on tuberculosis, hemophilia, and gastrointestinal diseases. In 1924 he and Professor Harry Steenbock announced independently the discovery that ultra-violet light from the sun, or its artificial equivalent, would impart antirachitic qualities to certain foods. In recent years, Dr. Hess conducted many significant clinical investigations on vitamin D milks, the results of which have been published in leading scientific magazines, including the *American Journal of Public Health*.

Dr. Hess was a graduate of Harvard and received his medical degree from the College of Physicians and Surgeons of Columbia University. He was a member of many scientific societies and had received numerous well deserved honors.

NEW YORK CITY DIPHTHERIA IMMUNIZATION CAMPAIGN

THE New York City Health Department and the medical societies of the Bronx and Queensboro conducted an immunization campaign in September and October. Children of parents unable to pay were given free treatment at the baby health stations. The campaign marked the use for the first time in general practice of the new precipitated and redissolved toxoid, the Health Department reported. The regular toxoid, however, was used for older children.

NEW OFFICERS OF TEXAS PUBLIC HEALTH ASSOCIATION

THE Texas Public Health Association announces the following nominations for officers of the Association for the ensuing year:

Dr. T. J. McCammitt, President; Dr. E. F. Yeager, First Vice-President; Dr. J. H. Page, Second Vice-President; Jack Wyatt, Third Vice-President; Zula L. Powell, Fourth Vice-President; M. Pierson, Secretary.

ARIZONA STATE SANITARY DIVISION

IN the reorganization of the Arizona State Department of Health, a division of sanitary engineering has been established with the aid of the Rockefeller Foundation. F. Carlyle Roberts, Jr., of Tucson, has been named state sanitary engineer, and has begun a survey of water supplies in the state.

IOWA DIPHTHERIA IMMUNIZATION CAMPAIGN

PLANS have been announced for a campaign to immunize children of preschool and early school age in Davenport, Ia. Members of the Scott County Medical Society will coöperate, and children of parents unable to pay will be treated at the Scott County Clinic.

Albert Calmette and Emile Roux

ON October 29, Dr. Leon Charles Albert Calmette passed away at the age of 73. After serving in the French navy and with colonial troops, he founded and became the first Director of the Pasteur Institute at Saigon, French Indo-China. Later he became Director of the Pasteur Institute at Lille. During the World War he was shut up in that city, and his animals were sacrificed, so that he was unable to supply any of the antitoxins to the children of that part of France. Since 1917 he has been Sub-Director of the Pasteur Institute at Paris.

Although he did an enormous amount of work on the purification of water, venoms and sero-therapy against venoms, he is perhaps best known for his masterly researches on tuberculosis and the production of BCG with his associate Guérin. He received many honors, having been granted the degree of LL.D. from Cambridge and an Honorary Fellowship of the Royal Society. In France he was Commander of the Legion of Honor.

On November 3, Dr. Pierre Paul Emile Roux, Director of the Pasteur Institute and one of the best known of Pasteur's assistants, died at the age of 80. He made a notable record along many lines, having directly assisted in the experiments which ended in the production of vaccine against anthrax and also the Pasteur treatment against hydrophobia. He is perhaps best known for his work on diphtheria. With Yersin (1888) he was the first to observe paralysis in rabbits following inoculation with diphtheria. In 1889, again with Yersin, he was the first to prepare diphtheria toxin and to study the conditions under which it is produced. He held that toxicity was not to be confounded with virulence of the culture, since potent toxin could be obtained from slightly virulent organisms. In 1890 appeared the paper which pointed out the importance in diagnosis

of the finding of the diphtheria bacillus, and described in detail the technic which with some modification has been followed since.

These studies were largely responsible for the activity in research on diphtheria which followed. At the International Congress of Demography held at Budapest, in 1894, he read a notable paper written by himself and Martin, which unquestionably gave a remarkable impulse to the use of antitoxin throughout the world. Roux and his coworkers were the first to use horses for the production of antitoxin.

He was an intimate friend of von Behring, to whom the credit must be given for first producing diphtheria antitoxin, but both read their papers at the same Congress, and to Roux is often ascribed the discovery of diphtheria antitoxin, though erroneously, since Roux began his paper with a clear statement that the credit belonged to von Behring.

We can ill afford to lose such men, and all over the world are many thousands who will join with France in doing them honor.

PUBLIC HEALTH MEETING IN IOWA

THE Iowa Public Health Association conducted its eighth annual meeting on November 22, at Des Moines. Dr. James P. Leake, U. S. Public Health Service, Washington, D. C., delivered an address on "The Recent Outbreak of Epidemic Encephalitis in St. Louis."

ENCEPHALITIS REPORTABLE

THE Board of Health of Macon and Bibb Counties, Georgia, recently amended its regulation governing communicable disease to include encephalitis as a reportable disease. In the future, patients must be isolated and quarantined, while placards will be required on homes where the disease is present.

Sickness Among the "Depression Poor"*†

G. ST. J. PERROTT AND SELWYN D. COLLINS, PH.D., F.A.P.H.A.

*Consultant, and Senior Statistician, U. S. Public Health Service,
Washington, D. C.*

THERE has been much speculation as to the effect of the economic depression on health, but no adequate index for evaluating its importance has been available. The usual barometer of health—or rather of ill health—is mortality. The general death rate and infant and tuberculosis mortality have declined during several years of severe economic stress to the lowest figures on record. This favorable situation has led some sanitarians to speculate as to the possible health benefits of the depression. They suggest that reduced excesses of eating and drinking and the lessened nervous tension that accompanies the quieter life of hard times, have actually improved health.

These interesting speculations are based on the number of people *dying* each year. Actually, mortality is a poor index of the health of the people. The death rate does not indicate the extent or nature of the 99 per cent of illnesses that are not fatal, or of physical im-

pairments such as malnutrition. Furthermore, an actual increase in mortality among the unemployed and their families could have taken place but have been entirely masked by the downward trend among the more prosperous elements of the population.

The purpose of the present study was to obtain at first hand a record of all types of illness among the families of the unemployed for comparison with similar data for the families of their employed neighbors. The information was secured by house-to-house canvasses of families in the poorer districts of industrial communities severely affected by unemployment.

METHOD AND SCOPE OF THE STUDY

The investigation obtained records of illness for a 3-month period in the late winter and early spring of 1933, and a 4-year income and employment record for each member of some 12,000 families in 10 localities. Eight large cities and 2 smaller industrial communities were canvassed. This paper includes preliminary data for 5 localities—Birmingham, Ala., Detroit, Mich., Greenville, S. C., Pittsburgh, Pa., and Syracuse, N. Y.

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

† From the Office of Statistical Investigations, U. S. Public Health Service and the Division of Research, Milbank Memorial Fund.

Only the poorer parts of the localities were surveyed. Well-to-do sections and slum areas were avoided. The desired sample of the population was one in which unemployment was high at the time of the canvass but which was composed largely of individuals of the wage-earning class who were able and willing to work. Living side by side with these families of the unemployed, there were other families who, even in these poor districts, were still in reasonably comfortable circumstances, that is, had adequate food, clothing, and shelter. These "comfortable" families serve as a control group whose illness record can be compared with that of their less fortunate neighbors. In the selected districts every family was included un-

less the information was refused, and refusals were exceedingly rare.

Although the enumerators were hired locally, the canvass in each city was in immediate charge of a person trained in the collection and tabulation of such data, who was assigned from the permanent personnel of the U. S. Public Health Service or the Milbank Memorial Fund. Because of prevailing economic conditions it was possible to get exceptionally good enumerators; they canvassed families only after careful instruction and trial visits with the local supervisor.

All persons worked under uniform written instructions. Thoroughness rather than speed was encouraged in the enumerators.

FIGURE I

Percentage distribution of the surveyed population according to annual family income per capita for each of the years 1929-1932. The population includes 20,283 individuals in 4,421 families in Birmingham, Detroit, Greenville, Pittsburgh, and Syracuse.

THE POPULATION SURVEYED AND ITS ECONOMIC HISTORY

In the 5 localities included in this paper, about 6,000 white families were canvassed. Of these schedules, 4,421 were sufficiently detailed to permit computation of exact family incomes for each year from 1929 to 1932, and were reasonably complete in other respects also. A total of 20,283 individuals is included in these families.

The usual occupation of the chief wage earner in 1929 was skilled laborer in 66 per cent of the families; unskilled 16.5 per cent; clerical and salesmen 10 per cent; dealers, merchants, etc., 6 per cent; professional 1.5 per cent. In 1932, in 17 per cent of the families the chief wage earner was without employment throughout the year and 19 per cent had received public relief at some time during the year.

In nearly 58 per cent of the families, the head of the household was native white of native parents, in 11 per cent of foreign or mixed parents, and in 31 per cent foreign born. The racial stock of the group of foreign or mixed parents was largely English, Irish, and German, but the foreign born included also considerable numbers of Polish, Italian, and Slavic stocks.

Income as used in this study consists of all receipts from any source, including savings and borrowed funds used for living expenses and the value of food tickets in the case of families receiving such aid from welfare institutions. Family income per capita was used as the basis of classifying the households because this seems to describe economic status more accurately than the total income which takes no account of the size of the family. Figure I shows the population grouped according to annual per capita income for the years 1929 to 1932. For convenience in discussion, the individual income classes have been combined into 3 groups and designated as follows:

Poor—\$149 and less per capita per year
Moderate—\$150–\$424 per capita per year
Comfortable—\$425 and over per capita per year

These names have no significance other than as convenient labels indicating a rising scale of per capita income.

Figure I shows the tremendous reduction in income which took place in the surveyed population during the depression. The "poor" group (\$149 or less per capita) which constituted only 13 per cent of the total in 1929, was equal to 51 per cent in 1932, while the "comfortable" group (\$425 or more) dropped from 37 per cent of the total in 1929 to 9 per cent in 1932. The percentage in the "moderate" class (\$150–424) did not change greatly. This does not mean that individuals in this group in 1929 suffered no diminution in income during succeeding years, but that as some dropped into the low income group, others from the higher class took their places. Actually, over half of those in moderate circumstances in 1929 had fallen into the poor category by 1932. Nine out of 10 persons classified as "poor" in 1929 remained in that state throughout the 4 years. Very few persons enjoyed an increasing income during the depression and a very large percentage suffered a drop in income.

ILLNESS IN DIFFERENT ECONOMIC GROUPS

Inquiry was made about illness from all diseases and accidents, including mild as well as severe cases. What was included as illness was to a considerable extent a matter of what the informant (usually the housewife) remembered and designated as such. Hence the records of disabling cases are probably better measures of real sickness than the total cases, because disabling illnesses were more likely to be accurately and completely reported.

Illnesses are classified as having (1) onset within the survey period and (2) onset prior to the survey period. Each of these groups is shown as (a) all cases, (b) disabling cases, consisting of those causing inability to carry on usual activities, and (c) cases in which the patient was confined to bed for one or more days. All bed cases are included in the disabling class. In the present paper, disabling case rates have been used exclusively.

The illness rates are for the 3-month

time of the canvass. The illness rate is higher for the lower income groups, when illnesses with onset within the survey period are considered. Illnesses with onset prior to the period (largely chronic cases) show no definite relation to income. For illnesses within the survey period, the disabling case rate in the lowest income group (\$149 and less) is 33 per cent above that of the group with an annual per capita income of \$425 and over. The poor in the surveyed group are obviously subject to

FIGURE II

Disabling illness during a three months period in the early spring of 1933 in wage earning families classified according to income per capita in 1932, in five surveyed cities. (Number of persons observed: \$149 and less, 10,424; \$150-\$249, 4,569; \$250-\$424, 3,353; \$425 and over, 1,937. Total 20,283.)

period of the survey and are not reduced to an annual basis. The "survey period" refers to the 3 months prior to the enumerator's visit; it is the period of time for which illness data were recorded. The actual canvass in each city required from 3 to 4 weeks. The dates of the canvass varied in the different localities but were all between March 20 and May 15, 1933.

Illness and 1932 income—In Figure II the incidence of illness is shown for 4 groups of the surveyed population classified according to annual per capita income in 1932, to show the relation between illness in 1933 and economic status approximately as it existed at the

time of the canvass. The illness rate is higher for the lower income groups, when illnesses with onset within the survey period are considered. Illnesses with onset prior to the period (largely chronic cases) show no definite relation to income. For illnesses within the survey period, the disabling case rate in the lowest income group (\$149 and less) is 33 per cent above that of the group with an annual per capita income of \$425 and over. The poor in the surveyed group are obviously subject to

more illness than their more fortunate neighbors in relatively comfortable circumstances.

Illness and income change—Families in the various income classes experienced different economic histories during the depression. For example, of the 10,424 individuals who were classified as "poor" in 1932, 23 per cent were "poor" in 1929, 60 per cent were "moderate," and 17 per cent were "comfortable." A further analysis of the relation between "depression history" and illness was made. For this purpose the individuals were divided into 6 categories according to economic status in 1929 and 1932, as follows:

I. Individuals experiencing materially lowered family income per capita between 1929 and 1932 were classified:

1. Comfortable in 1929 and poor in 1932
2. Moderate in 1929 and poor in 1932
3. Comfortable in 1929 and moderate in 1932

II. Individuals who had not experienced materially lowered family income between 1929 and 1932 were classified:

1. Comfortable in 1929 and 1932
2. Moderate in 1929 and 1932
3. Poor in 1929 and 1932

showed an incidence of disabling illness that was 55 per cent higher than the rate (87 per 1,000) of their more fortunate neighbors who were equal in status in 1929 but suffered no drop in income by 1932, that is, the "comfortable in 1929 and 1932" group. The families which had dropped from comfortable to moderate showed a 10 per cent higher disabling illness rate than the above group that had experienced no drop in income. The group which had dropped from moderate to poor

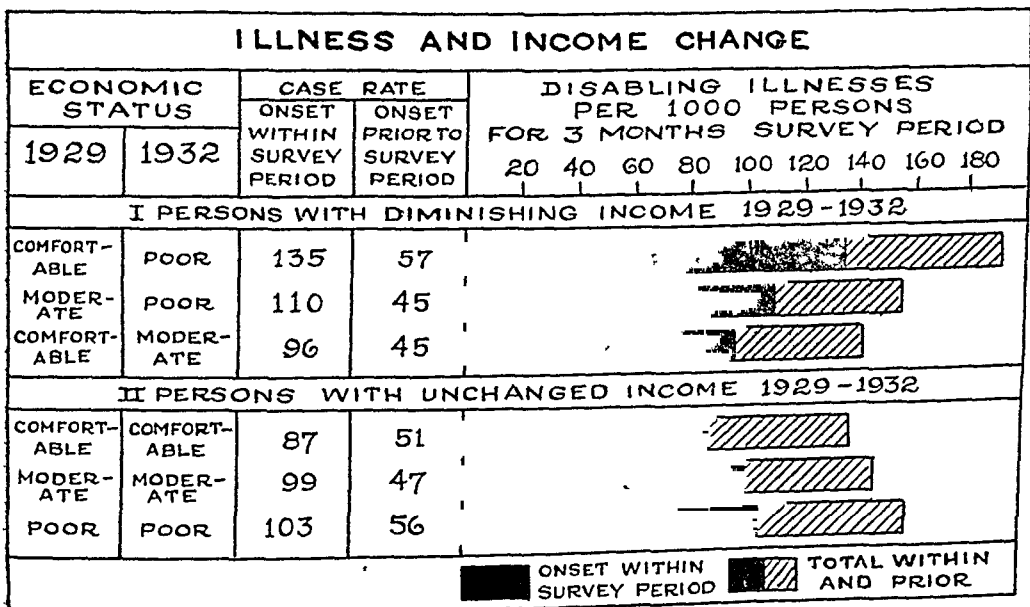

FIGURE III

Comfortable = \$425 and over per capita per year

Moderate = \$150-\$424 per capita per year

Poor = \$149 and less per capita per year

Disabling illness in wage earning families classified according to change in economic status, 1929-1932, in 5 surveyed cities. (Number of persons observed: Comfortable-poor, 1,772; Moderate-poor, 6,209; Comfortable-moderate, 3,919; Comfortable-comfortable, 1,818; Moderate-moderate, 3,761; Poor-poor, 2,443. Total, 19,922-361 persons with higher income in 1932 than in 1929 are omitted.)

Sickness data for these groups are given in Figure III. The highest illness rate is experienced by individuals whose fortunes have suffered the greatest change, namely, the group comfortable in 1929 and poor in 1932. This group with a rate of 135 per 1,000

show an 11 per cent higher illness rate than those that were in moderate circumstances throughout the 4 years. It is interesting to note that the groups which may be designated as the "depression poor," that is, the "comfortable 1929-poor 1932," and "mod-

FIGURE IV

Comfortable = \$425 and over per capita per year

Poor = \$149 and less per capita per year

Disabling illness at specific ages in 5 surveyed cities in 2 groups of wage earning families, one which suffered a large decrease in income between 1929 and 1932 (comfortable 1929—poor 1932) and the other which maintained unchanged income (comfortable 1929 and 1932).

erate 1929—poor 1932,” have a higher illness rate than the “chronic poor,” i.e., “poor 1929—poor 1932.”

The same trends are observed for the total illnesses, onset within the survey period, and even the addition of the cases with onset prior to the survey period (largely chronic) does not obscure the fact that a relatively large drop in economic status appears to be associated with a high illness rate.

Figure IV shows the age-incidence of disabling illness in two groups, “comfortable 1929—poor 1932,” and “comfortable 1929—comfortable 1932.” It will be seen that for illnesses with onset within the survey period the “comfortable—poor” group shows a higher rate of illness than the “comfortable—comfortable” class in each of the 5 age groups used. The chronic illnesses appear to be slightly higher in the “comfortable—comfortable” group up to about 25 years. Above that age, the chronic cases, like the acute, are less in

this group than in the “comfortable—poor” class.

Respiratory diseases account for the larger proportion of the difference in illness rate between the “depression poor” and their more fortunate neighbors. However, the differences are still evident in the group of non-respiratory diseases. The children of the “depression poor” show a higher incidence of respiratory diseases than the children of the families which were unaffected in economic status by the depression. This difference is not evident in the communicable diseases of childhood such as whooping cough, measles, mumps, etc.

Illness and unemployment—Since a high incidence of illness is associated with low income, it would be expected that families containing no employed workers or part-time workers only would show a higher illness rate than families having full-time workers. Figure V indicates that this is true at each

FIGURE V

Disabling illness at specific ages in 5 surveyed cities in families classified according to employment status of wage earners. Data for all ages: Unemployed or part-time: Onset within—116 per 1,000; Onset prior—53 per 1,000; Population, 11,785. Full-time: Onset within—88 per 1,000; Onset prior—42 per 1,000; Population, 8,498.

age and for both acute and chronic conditions.

SUMMARY

Records of illness in 1933 and economic history from 1929 to 1932 have been collected on over 12,000 families. The present paper presents preliminary results of the survey in 5 cities—Birmingham, Detroit, Greenville, Pittsburgh, and Syracuse. This group comprised 4,421 families and included 20,283 individuals.

The results show a higher incidence of disabling illness among individuals in the lower income classes in 1932 than among individuals with higher incomes. Illness is highest among a group of the "depression poor" which was in reasonably comfortable circumstances in 1929 but had dropped to comparative poverty by 1932; their rate is higher than that of their more fortunate

neighbors who suffered no drop in income and higher than the illness rate of the "chronic poor" who were in a condition of poverty even in 1929. Families containing only unemployed or part-time workers show a high incidence of disabling illness.

The writers have purposely refrained from drawing conclusions as to the broad significance of the findings. For example, no attempt has been made to estimate the number of the whole wage-earning population of the United States which has had a similar history to the group surveyed in the 5 localities. Nor is it possible to judge the seriousness of the situation indicated by the increased illness rates observed among the "depression poor" until the nature of the sickness is analyzed in more detail. Such interpretations must await more complete analysis of the entire volume of data collected.

The Growth of American Cities*

HOWARD WHIPPLE GREEN, F.A.P.H.A.

Secretary, Cleveland Health Council, Cleveland, Ohio

THE phenomenal growth of American cities is known to everyone. How New York City with a population of 49,401 in 1790 became a city of 6,930,446 inhabitants; Chicago with a population of 4,470 in 1840 within less than a century became a city of 3,376,438; and Philadelphia with a population of 28,522 in 1790 became a city of 1,950,961 inhabitants; Detroit with 1,422 in 1820 acquired enough people to make 1,568,622 in 1930; and Los Angeles with a population of 1,610 in 1850 in 80 years came to exceed 1 million, and to have a population of 1,238,048 is common knowledge.

It is not so well understood why Lynn, Mass., with 2,291 in 1790; New Bedford, Mass., with 3,313; Cambridge, Mass., with 2,115; Albany, N. Y., with 3,498; Norfolk, Va., with 2,959; Springfield, Mass., with 1,574; a total of 15,750 inhabitants for the 6 cities collectively in 1790 only had a population of 735,582 in 1930 while another 6 unheard-of places with no populations in 1790 had 9 million inhabitants in 1930.

Neither is it so clearly realized that Lowell, Mass., lost population between 1920 and 1930 as did Wilmington, Del., New Bedford and Fall River, Mass., and a multitude of other large American cities gained so small a number of inhabitants as to have no significance as indicating continuing growth.

For example, is Boston continuing to

increase in population when it had only 33,128 more in 1930 than in 1920 and changed from 748,060 to only 781,188?

With talk on all sides about the near approach of an ultimate maximum population for the United States, about our decentralizing industry and about the enormous effect upon population distribution which is being exerted by the automobile which provides a dependable mode of rapid transportation, one hardly knows whether or not to provide for larger and larger populations within metropolitan areas.

May decentralization of industry from within our large industrial centers be assumed to cause these centers to turn more to trade, finance, and transportation, in order to occupy their inhabitants? or may their populations be expected to decrease?

I shall not attempt to answer these questions in the space allotted to me, for what would be true for one place would be ridiculous for another. However, realizing that the provision of potable water and satisfactory disposal of sewage, to say nothing of the paving of streets, provision of gas, electricity, and telephone service, refuse disposal, transportation facilities, and a multitude of other important services, is a problem which must be faced months and years before the demand has arrived, I wish to consider with you some of the more basic factors of population growth.

If the City of Cleveland of 1830 had remained constant as far as its geographical boundaries were concerned, the population curve would show in-

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

creases from 1,076 in 1830, to 9,090 in 1870 and decreases from 9,090 in 1870, to 1,691 in 1930 and to far less than that population in 1933.

The City of Boston of 1840 would have shown an increase from 93,383 in 1840, to 178,086 in 1910 from which time it would have shown decreases to 148,040 in 1930. And the City of St. Louis in 1840 of 16,469 would have shown increases to 32,000 in 1870 and decreases since that time to a population of 5,634 in 1930.

In other words, these cities increased in population by annexing adjacent territory and the resultant increases may be credited more particularly to population accruing to the annexed territory.

For example, the most important annexations to Cleveland occurred between 1870 and 1880 during which period territory was annexed, having, in 1880, a population of 28,235 which by 1920 had increased to 295,822 and accounted for 37 per cent of the entire population of the city in that year.

So much for the growth of the total population of cities. I have already gone rather thoroughly into this subject in an article written for the *Engineering News-Record* of February 9, 1933.

The provisions of certain community services such as water purification, sewage disposal, garbage incineration, etc., are almost entirely dependent upon total populations. However, other similar services are only of use in the area in which they are located. For example, if an area of the city such as census tract J-1 in Cleveland is provided with sewer pipes of ample size for the 6,114 people inhabiting it in 1910, and its population decreased to 49 people in 1930, census tract T-8 which increased from 59 in 1910 to 10,577 in 1930, receives no benefit from the excess facilities in census tract J-1.

Such changes are going on in our

larger metropolitan communities all of the time. Careful studies of population trends should pay huge dividends in any large community.

The ability to prognosticate ultimate maximum populations is of considerable advantage in many instances, especially if determined for small geographical areas. Some approach has been made to supplying the necessary basic data for such studies in Cleveland through the "Real Property Inventory of the Cleveland Metropolitan District" in which data for 321 small geographically constant areas or census tracts have been made available.

As an illustration of the use of these data let us consider the City of Lakewood adjacent to Cleveland on the west. Lakewood in 1900 had a population of 3,355; in 1910, 15,181; in 1920, 41,732; and in 1930, 70,509. Lakewood was showing a steady and substantial increase in population and it might be prognosticated that a population of 100,000 more or less would be enumerated in 1940. However, the Real Property Inventory data of October, 1932, showed 20,572 family-units in Lakewood, 18,854 occupied and 1,718 vacant, in contrast to 19,635 occupied in April, 1930. It also showed that there were but 985 vacant lots and 25 acres of unallotted acreage. If it may be assumed that none of the area will be used for retail or for commercial enterprises and that each lot will ultimately be used for a single-family dwelling and each acre will provide 5 lots, it may be expected that only 1,110 additional family-units will be created. Thus a population of 78,000 living in 21,682 families may be assumed to be the ultimate maximum.

A study of the number of lots created each year, the number used for buildings, and the number of buildings demolished each year, aids in prognosticating population changes both immediate and ultimate.

These factors and scores of others must be taken into account when plans are made for public improvements. There is no use of providing wading pools when the population is too old to wade, schools when the child population is decreasing, or additional telephone conduits when the economic status of an area is declining. Our studies of the number of families with telephones show but 6.1 per cent of the families having telephones in the lowest economic area as contrasted to 99.5 per cent of the families in the highest economic area. In the lowest area 15.5 per cent of the families had a radio set and 14.4 per cent had one

or more personal automobiles in 1930 while in the highest economic area 87.4 per cent had a radio set and 93.2 per cent an automobile. The consumption of water and the volume of sewage to be carried away, may be expected to vary enormously with economic conditions.

I was originally asked to discuss the question: "Are cities likely to grow?" You can see that I have evaded the question very completely but in doing so I have attempted to present for your consideration some of the basic reasoning necessary to answer the more pertinent question: "Is a specific city likely to grow and if so how much and in what direction?"

New York Speech Center Broadens Activities

AFTER 16 years as an institution licensed by the New York State Board of Charities, the National Hospital for Speech Disorders has moved into its new quarters, 126 East 30th Street, New York.

This is the only institution of its kind, devoted solely to the cure of

speech defects, and devoted mainly to pathological conditions of voice and speech; the scope of activities is now to be broadened, however, to include special instruction in radio broadcasting, public speaking, dramatics and other features for normal speaking persons.

Keeping Up With the Demand for Adequate Pure Water*

HARRY E. JORDAN, F.A.P.H.A.

Filtration Engineer, Indianapolis Water Company, Indianapolis, Ind.

IN the consideration of this somewhat encyclopedic title, I shall confine the discussion to four major questions.

1. What is the probable trend of water demand among American cities?

2. What physical elements in public water supply need particular strengthening to meet this probable demand?

3. How does water works operating personnel measure up to its responsibility?

4. What may we assume to be the trend in water supply quality?

The trend of demand for water is dependent upon two factors—population growth, and variety or extent of water use.

1. There is beginning to be a reasonably wide appreciation of the fact that the United States is much nearer its population peak than was estimated a few years ago. This idea naturally must have underlying it the reservation that, just as Malthus' prophecy was upset by changes in the the industrial order, so also our present ideas as to living planes may be upset.

Assumption as to limits of population growth in the continental United States are predicated upon the maintenance of a scale of living and comfort—no lower—probably higher than at present obtains. Naturally, if some social catastrophe lowered the living standards now assumed to exist gen-

erally in this country, the capacity of the tillable areas to provide subsistence would permit a population density equal to that which obtains in certain Asiatic areas. We are all familiar with the population projection of Raymond Pearl which predicted the upper limit of the present cycle of growth at about the year 2100 with a total for the continental area of 197.274 million persons. This estimate was made before the implications of our national reversal of immigration policy were as much appreciated as they are now. The drastic change in this regard not only has reduced the annual increment of adult foreign population but has also affected the national birth rate.

The decade 1905-1915 witnessed annual net increments by immigration ranging from 400,000 to more than 800,000. In 1931 the admission-departure balance sheet evidenced a net departure of more than 10,000 persons. In addition to this a decline in births has been effective since 1924. The net result of these changes has led Thompson and Whelpton to set the upper limit of our present cycle of population growth to be reached in 1980 with a total of between 145 and 170 million persons. Taking the upper figure for purposes of this discussion, the estimated growth represents a 40 per cent increase over 1930 figures. It means naturally from a practical standpoint that some cities most favorably situated may double this rate of growth and that others in the +100,000 class

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

less favorably situated may show little or no growth. From an over-all water supply standpoint—upon the population basis alone—it appears rational for water supply authorities in cities where evidences of stasis or decay are not apparent, to cast about, within the next 25 years, for an ultimate increase in supply facilities from 40 to 60 per cent above present demands.

Influencing all matters of this sort, is the present national development in the direction of controlled capital investment. It is not in the least fanciful to assume that a material influence upon community and sectional growth may result from the changed emphasis upon capital input from the field of capital goods to producers' goods. We may also witness a more rapid decentralization of population masses under the influence of a social organization that limits the hours of employed labor and increases the hours of so-called leisure.

These influences upon urban growth cannot be estimated at the present time with any such degree of accuracy as to relate them directly to the questions in hand. Suffice it to say that the city with $\frac{1}{3}$ million inhabitants at the last census period should set its planning eye, not upon 1 million population as was the order of the day not so long ago, but upon $\frac{1}{2}$ million or thereabout.

In the category of varieties of water use, must be considered one factor that already has been placed upon its proper basis in most cities but which still in a few makes a rational approach to water supply problems well nigh impossible. To be exact, public water supply cannot be intelligently planned and administered unless the consumption is metered. It is an easy way out to say that citizens should have all the water they want to use, but such an attitude evidences a degree of naïveté unworthy of engineers, and more characteristic

of witch doctors. Human nature is a bit rawer than many wish to admit, and one way in which the old Adam breaks through is in the wilful and inconsiderate waste of water from unmetered supplies. Fortunately here again, the current limitation of capital input has a distinct bearing. The growth of consumer demand upon an unmetered supply brings a property to the point that it is not self liquidating. Conservation of present supply must ensue.

In cities where the supply is metered the present per capita demand ranges from 100 gallons per day in areas with a 35/45 inch annual rainfall to +150 gallons in semi-arid areas. But it appears that the demand even in the higher rainfall areas is increasing as equipment for lawn spraying is more widely sold and the development of pool and garden areas increases. Likewise there is a definite increase in the use of water for personal cleanliness, and we appear to be upon the verge of use of water for home air conditioning. Doubtless the latter will make no spectacular per capita increase in demand but it, along with other increasing uses of water, will influence total community demand materially.

2. What physical elements in public water supply need strengthening to meet current or future demands? Principally those relating to continuity and uniformity of service. The point may be better understood by reference to the improvements that have gone on in the electric utility field. Not so long ago it was not uncommon for voltage to drop noticeably under heavy load conditions and for current to fail completely for long periods after thunderstorms. Now a noticeable voltage variation in a sizable city is a rarity and even during the most severe electrical storm current interruptions are only momentary. It is this reliability of service that has led to increased use of current. Many of us depend upon the

mechanical regularity of electric current to operate our timepieces and check their accuracy by the radio announcement.

No such advance has been made in water supply practice. Too frequently it is assumed that peak loads or emergencies can be met by partial—often unreasonably inferior—service. It is difficult to justify such complaisance, especially in a city where service is metered. The greater the consumer demand, the greater should be the effort to render service. But it is in this phase of water supply practice that the greatest field for improvement lies. Most noticeable is the failure, even at present rating, to comply with the requirements of the National Board of Fire Underwriters. The following phrases from their rating *Manual* summarize the requirement adequately:

Reliable fire protection requires such duplication of all parts of a water system that with such parts out of service as may reasonably be expected to be inoperative, the system will still be able to furnish the required fire flow. The introduction of storage, either elevated and supplying the distribution system or for suction supply, offsets to a greater or less degree the need of duplication in various parts of a system, the value of the storage depending upon its amount and location; as affecting reliability of supply, it appears to be a reasonable assumption that a storage sufficient to provide fire flow for 10 hours during a period of 5 days of maximum consumption is sufficient to permit the making of most of the repairs, alterations or additions incident to the operation of a water supply system. . . .

Reliability of Pumping Capacity on which supply is dependent, shall be on the following basis:

Pumping capacity must be such, with the two largest pumps out of service, as to maintain maximum consumption and fire flow at required pressure. . . .

A water utility must produce a water meeting all hygienic requirements and having regularly a taste and odor which will produce a favorable consumer reaction. The supply must be adequate for all normal domestic and industrial

demands of the city; it must meet all demands for fire protection purposes and it must not be subject to restrictions or interruptions by drought on the one hand or floods on the other. We may reasonably demand that a water utility shall apply whatever lessons it may have learned from drought experiences in providing against a repetition of water shortage, and we may also demand that it protect the consumers against water shortage at times of flood, if in its history it has records of interruptions to service by reason of plant inundation.

The volume of available water is but one of several factors which must be analyzed in considering the necessity of plant extensions or alternate supplies. It is quite conceivable that a water utility might have at its command raw water sources materially greater than its maximum demand but of such quality that it was not a desirable source for purification. It is also conceivable that a water utility might have present sources of supply marginal as to quantity at time of drought, where the present evidence gained over the country in the 1930-1931 drought would indicate that it is dangerous to consumer comfort to use to the last drop a surface water for purification sources. We may also visualize a supply marginally adequate of a quality suitable for purification purposes, which has a sufficient record of interruption during flood periods to indicate the engineering wisdom of supplementing it with a separate and distinct source of supply not subject to flood interruptions.

We may also learn from the practices of other cities that when they reach a certain size and importance it is desirable to separate their water supply facilities into units of such size and distribution as to make possible at least a partial service from one source if the other is unavailable for a short period.

Such type of development has occurred in Cleveland, Detroit, St. Louis, Minneapolis, and Chicago. In these cases factors in production as well as distribution have led to the development of widely separated production layouts where it is still conceivable that production might have been developed from one point.

Volume of water is one factor in choice of water supply sources. Freedom from interruption by inundation is another. Separation of supply units for safety's sake is another. Degree of response to purification methods is another—all must be taken into account in developing a city's water supply sources.

In all engineering practice, it is common to protect against unforeseen matters by a factor of safety. What this factor or margin in terms of quantity should be is difficult to evaluate. The Chief Engineer of the New York City water supply has recently stated that it should not be less than 10 per cent of the available sources. In my opinion this factor should increase for cities of moderate size up to probably 25 or $33\frac{1}{3}$ per cent of the previously recorded minima. An incipient conflagration at the height of a dry period might be checked by that margin of safety, while a "let slide" policy would have exhausted that margin. It is easy to visualize "getting by," but cities have a way of not forgetting catastrophes.

3. In the attempts to meet the demand for adequate pure water, how does water works operating personnel measure up to its responsibility? Even in the phase of maintenance of safe quality, the record is not one in which we can take pride. Wolman and Gorman did a major service to the field of public health engineering when they made and published their study upon "The Significance of Water-Borne Typhoid Epidemics." Let us get into

the heart of it. In their summary of the factors responsible for all cases of water-borne typhoid fever and dysentery in the United States in the period 1920-1929, they ascribe 54.1 per cent of the total to "inadequate control over purification methods." Under this heading they include (a) inadequate control of filtration and allied treatment, (b) inadequate chlorination, when only treatment, (c) interruption of chlorination when only treatment.

It is not important that we at present go through the details of their analysis to see whether we agree with their allocation of the causes. Grant, if you wish, that they were wrong half the time and you are still compelled to charge against bad management of water works plants one-fourth of all the water-borne urban typhoid and dysentery in the United States. Either amount represents so great a failure as to be a tremendous indictment of our water works operating personnel. Why did this happen? What can be done to correct it?

One of the principal reasons for the happening is that our municipal authorities have treated minor (sometimes major) water works operating personnel as political spoils. The qualification for selection has not been "competence for water works operating duty," but "votes delivered in the precinct." Along with this has developed the condition that men in responsible positions in the department were not allowed sufficient authority to build up and maintain an efficient operating organization. Full administrative authority to employ or to discharge subordinates is a prime requisite for successful administration of a water purification plant.

The community that puts purification plant operating responsibility upon an individual and does not give him an organization plan that carries with it control of his subordinates is inviting a

water-borne epidemic as certainly as water flows downhill. I shall not forget the sadness in the face of one purification plant superintendent who said to me "I have no time any more for research—it takes all my time and energy to keep from being thrown into the political den of lions and to produce some sort of civilized routine out of this mess of ward hangers-on that I have been given to operate the plant."

Naturally along with improvement in minor personnel and their performances, goes the need for never-ending energy and search for improvement among those in responsible charge of operations. There comes to mind the sentences of Lewis Carroll in *Through the Looking Glass*:

"Well, in our country," said Alice, still panting a little, you'd generally get to somewhere else—if you ran very fast for a long time, as we've been doing."

"A slow sort of country!" said the Queen, "Now, here, you see it takes all the running you can do, to keep in the same place. If you want to get somewhere else, you must run at least twice as fast as that!"

Such is the life of a water plant executive—if he does his part to overcome the disgraceful record of water-borne typhoid during more than half the last decade, some dysentery also being ascribable to failure properly to control processes known to be effective in producing safe water supplies.

4. Finally—What may we assume to be the trend of demands for quality of water supply? A satisfactory water in present-day conception of the terms may be described as follows:

A water supply to be of high quality, should be clear; of neutral taste; of reasonable temperature; so balanced chemically that it neither dissolves materials excessively with which it comes in contact, nor deposits portions of its mineral content thereon; and neither produces unfavorable physiological effects nor contains organisms capable of producing intestinal infection.

Correlative to the expression as to finished water quality we may set a

statement as to the limiting characteristics of a source from which a public water supply should be derived:

A public water supply should not be produced from a source containing taste producing materials that cannot be removed by reasonable methods, whose temperature frequently exceeds that of the human body; so polluted by trade wastes or natural materials from the watershed as to contain an irremovable color or irremovable mineral salt of adverse physiological effect; nor so polluted by sewage as to preclude adequate purification by well known and practicable methods.

In meeting purification problems, the water supply engineer is at the mercy of a public (the same public that permits political control of its water works), far too often indifferent to the needs of adequate sewage treatment. The callousness with which one city destroys the recreational value of a stream for its own people and at the same time makes more difficult the water purification problems of its downstream neighbor confirms one in the orthodox opinion of the fallen nature of mankind.

By and large, the extreme zeal with which water plants have undertaken taste correction deserves tribute. Their energy is commendable, but we must not, in our enthusiasm for taste corrective treatment, forget that the need of such treatment results from the unreasonable overloading of the source stream with the waste products of other communities.

Fortunately — or unfortunately — as we may choose to view it, the approach to a density limit of sewage organisms in a raw water is definite. Various expressions of this have been made, but none so definite as that of Streeter at the close of his long series of studies of performance of purification plants. Whether or not one agrees with the reasoning, he at least must defend against the indictment the use of any raw water whose average *B. coli* content

exceeds 5,000 per 100 ml. It is reasonable to expect that in any future revision, the Treasury Standard limitations will not only be set as they are now upon the quality of finished waters, but also may be suggested as to limiting average *B. coli* index of raw waters.

It is difficult to visualize a rational objection to such development in the light of the experimental evidence at hand. My own organization has already admitted the validity of this opinion, by refusing to consider as satisfactory under drought conditions an emergency supply to be taken from a stream whose *B. coli* index is above the 5,000 average and into which a number of combined sewers may discharge within a 5 mile distance above the intake. In spite of the contention of our adversaries in a rate case that the supply could be considered useful under low flow conditions, our policy has been steadfastly to regard the supply as usable as a raw water source only as an emergency reserve. More cities than now care to admit it will face the issue either of obtaining more adequate purification of upstream sewage or supplementing their present sources with raw water that conforms to the approaching standards.

The overloaded stream is less likely to manifest its condition by a continuous ill-effect upon the public health of water users than it is, at time of sudden changes in flow to furnish a water non-responsive to purification processes which are generally adequate. Such conditions may be followed by those painful, brief, and generally non-serious intestinal outbursts which involve a very large proportion of the city's popu-

lation. We lack adequate data from the medical profession on the subject, although it is probable that they come into contact with only a small proportion of those affected. Certain recent research has indicated that staphylococcus and streptococcus filtrates experimentally produce intestinal disorders not dissimilar to those occurring in the Charleston, W. Va., epidemic of 1930. If this is substantiated by other observers, it becomes all the more definite that the stream with the high average *B. coli* density and the probable peak densities beyond the scope of purification processes may not be continued as a source of supply for a purification plant.

In brief, the task of keeping up with the demand for adequate pure water appears to forecast the following: The present cycle of national growth indicates an average ultimate increased demand upon water supply facilities 40 to 50 per cent above present normal demands with the usual allowance for peak and fire demands. Water supply works in general need to improve physical structures so as to effect regularity and adequacy of supply under peak demand conditions. Water works operating personnel generally suffers by reason of misuse of political patronage. Specifically, the recent record of purification plant failures distinctly challenges those in responsible positions to train themselves and their subordinates to a much higher degree of performance. Finally it is evident that a stricter limitation of raw water quality must force either improvement in stream loading conditions or the abandonment of unreasonably loaded sources of supply.

Liquid Wastes Their Treatment and Disposal*

LANGDON PEARSE, F.A.P.H.A.

Sanitary Engineer, The Sanitary District of Chicago, Chicago, Ill.

IN the past 30 years marked advances have been made in the treatment of liquid wastes of cities and industries, due to a better understanding of the principles of biochemistry and physical chemistry and their application to the sewage art. Further, the mechanization of the sewage works has progressed, both by design of special devices, and by adaptation of apparatus used in other fields. Such progress in the art however has probably been more helpful to the large installations than to the small. For a town of 10,000 population more or less the types of sewage works available have become more or less stabilized. The changes now occurring apply chiefly to the larger situations where economies in construction and operation show up more markedly because of the scale. More and more the yardstick of cost is being applied, because sewage disposal *per se* is always in the red and the object is to keep the losses as low as possible.

There is probably no installation in the United States or for that matter in the world, where sewage disposal makes an over-all profit. Possibly the City of Bradford, England, earned a return in one year during the World War which covered all annual charges.

Industrial waste treatment may prove a different story in some cases, such as the corn products industry, where the bottling up of wastes and recovery of the solids is said to have produced a considerable revenue. The use of save-alls in paper mills, and the recovery of fats, fertilizers, and other by-products in the meat packing industry, are examples of what has been accomplished at an earlier stage. But in many industries, treatment of the liquid wastes will probably be a charge against the manufactured product and not a source of income.

The demand for clean streams and for palatable water supplies free from tastes and odors is bringing home the need of greater care in the treatment of sewage and industrial wastes. An interesting example is the pollution of the southern end of Lake Michigan by the sewage and industries in Lake County, Ind. On one occasion, the wastes from the industries (including an oil refinery) were swept by windblown currents some 50 miles north, to produce unpleasant tastes in all the water supplies taken from that frontage.

What are some of the high points in progress in the art? To my mind, first comes the improved methods in laboratory procedure, enabling the sanitary engineer to study the problems better and to determine in advance the effect of what he proposes to do. The biochemical oxygen demand is a marked

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

improvement over the old line methods—furnishing a yardstick of efficiency for processes as well as a means for testing stream purification. Likewise the introduction of pH control to the sanitary field has been a great aid in shedding light on many problems.

Next come the improvements in design made possible by the careful tests of many large works and operators generally throughout the world. Construction costs have been lowered through the combination of steel and concrete, and of the application of large scale construction methods. Not to be forgotten are the operating results, both in cost and efficiency, whereby the operators of sewage works are building up a mass of invaluable data.

The sewage art is divided now very definitely into two fields,—the treatment of the liquid and the treatment of the solid. In the last 10 years the treatment of the liquid has attained more stability, and the treatment of the solid, the sludge problem, has been advancing.

In the treatment of the liquid, the activated sludge process stands out, disclosed to the public by Ardern and Lockett, April 3, 1914. The revival of interest in chemical precipitation has awakened the old discussion of the relative merits of biological and chemical processes. Little that is really novel has been brought forward, unless it be in the Guggenheim process where zeolite is used to remove free ammonia after chemical precipitation. Dr. Mohlman will discuss the subject of chemical precipitation later. All I wish to emphasize is that there is still much to be learned from the lessons of the past. There are physical, bio-chemical and chemical laws which work. While a knowledge of pH control may help understanding and operation, it is not a panacea. A yardstick of performance is available in the BOD test. With the tools at hand the sanitary engineer

will gradually determine what the efficiency is of each process, and rate it accordingly.

In the handling of solids many interesting lines have been developing. Practice, however, until recently, stopped short of one final goal, an inert mass free of all organic matter. The Imhoff tank and separate digestion stimulated by heat, have worked well in many situations. Likewise the development of mechanical means for cleaning air-drying sludge beds, and the use of glass covers have been helpful. The application of vacuum filters to dewatering properly conditioned digested sludge has been another step—Whether raw sludge can be so handled and dumped with impunity is still in doubt. However, fresh and activated sludges generally contain considerable amounts of heat units per pound of dry solids. After dewatering on a vacuum filter with the aid of a conditioner, the resulting cake may be dried and burned, with relatively small additions of fuel. The residue is inert, and practically free from organic matter. The possibilities of this procedure are being tested on a relatively large scale by the Sanitary District of Chicago, with two 25-ton dry solids installations. Such a procedure may eliminate both sludge digestion and air drying beds and make appreciable reductions in first and operating costs on a complete plant—using preliminary settling and activated sludge.

Progress has been made in the sludge disposal field. Milwaukee is an example in commercial marketing of heat-dried activated sludge as fertilizer. Smaller cities, like Grand Rapids or Dayton, are marketing heat-dried digested sludge locally. Baltimore gives away to truck farmers all its sludge as removed from the drying beds. The material has value as humus and as a fertilizer according to the type.

Much has been learned of the effect on the stream of an effluent. Where the

dilution is low, there is need of investigation to determine what secondary nuisances may arise from plant growths. Again, where combined sewers are in service, the problem of storm water control or treatment is coming to the fore in situations where some years back the question did not arise.

The coöperation of the engineer, chemist, and biologist is bearing fruit. Organizations like the New Jersey Sewage Experiment Station, the U. S. Public Health Service, the Sanitary District of Chicago, Baltimore, Milwaukee, and the Sanitary District of

Indianapolis are aiding in collecting knowledge and making facts available for general use.

As the art progresses, the opportunity for a great improvement grows less, but there is still opportunity for betterment. Sanitary science provides means which can be adapted to many situations. For the large concentrations of population the sanitary engineer is now concerned with the adaptation of new or special methods, particularly where savings in cost and betterments in results may be accomplished because of the size of the problem.

Can Refuse Collection and Disposal Systems Be Improved?*

HARRISON P. EDDY, JR., F.A.P.H.A.

Metcalf & Eddy, Engineers, Boston, Mass.

IT is possible to look forward with a feeling of considerable hope to an improvement in the administration of those of our municipal utilities in which operation is based primarily on engineering principles. Among such may be included our refuse collection and disposal services. While in many of our cities this work is done today with efficiency and economy and a proper appreciation of the engineering principles involved, nevertheless in many of our cities and towns it is believed that these principles are not thoroughly appreciated. With the tremendous increase in the number of our technical uni-

versity graduates and technological unemployment it is probable that many more technically educated engineers will participate in the routine operating services of our cities.

A substantial improvement may be obtained in cities which adopt a service charge against the householder, for the operation of the collection and disposal works, particularly if the money so received is ear-marked for the sole use of the refuse collection and disposal department. In this way this department may become independent of the appropriating power of the city government and thereby may have funds available for proper maintenance of equipment and increase in plant when this may become necessary.

While many directors and employees

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

now are competent, experienced men, there often is room for substantial improvement by rigid adherence to the policy of basing all appointments solely on merit.

There is substantial room for improvement in design of our refuse disposal works. Improvements in design will tend first toward greater life of the equipment; better provision will be given to withstanding the resistance to operating conditions which cause deterioration; operating conditions will be simplified and improved. Already substantial advance has been made in this direction. With the purchasing of disposal works, based on the engineering merits of the design, a great forward step will be taken.

The greatest single advance in refuse disposal will come in improvements in operation. When the engineering principles involved are properly appreciated, incinerators for example will be operated at a uniform rate throughout the day, rather than at a high rate for a short time, followed by complete cessation of operation. Alternate heating and cooling of the refractories permits periods of low temperature operation during which combustion may not be satisfactory, and sudden temperature changes cause rapid expansion and contraction of materials and rapid deterioration of the plant in general. Basing the capacity of a plant on 24-hour operation instead of 8-hour operation, permits a great decrease in the capital invested and in the fixed charges per ton of material disposed of.

Greater attention should be given to the maintenance of cleanliness about disposal works. While this seems trite, there can be no question that rigid cleanliness in a plant dealing with material of this nature in such tremendous volumes will result (1) in a much higher morale among the operating staff; (2) a coincident improvement in the care given the physical equipment with

a corresponding increase in its life; (3) more efficient operation because of the pride taken in the work; (4) greater respect for the operation of the department, among the public and the city officials who appropriate the funds required for operation. This will make it possible to secure the funds needed more easily than with careless methods of operation.

So far we have dealt only with the disposal system. The collection system is an entirely different function, but susceptible to great improvement due to the same basic factors. There is a tremendous variation in the type of equipment used for this service, thus calling for sound engineering study of the requirements of the city in selecting suitable equipment. There is apparently a greater tendency to assume that European methods are superior to ours in the field of refuse collection than in any of the other municipal services with which public health engineers customarily deal. While much has been said of the difference between the material collected in Europe and in this country, I doubt if this difference is always appreciated, and little is said of the difference in wage rates in Europe and in this country. Both of these factors should be given serious consideration in comparing foreign practice with home practice.

Possibly the greatest single opportunity for improvement in collection services lies in studying the various problems which arise, *on a unit basis* such as the work done in cubic yards, tons, man-hours, vehicle-hours, and ultimately in dollars per unit, rather than by reasoning in generalities from a comparison of the total costs of one city with those of another. Probably there are no two cities where the per capita cost of an equally efficient service using identical equipment would be the same, due to the many variable features in the problem, such as different street

layouts in the two cities, different topography, different operating personnel, and many other features.

There is no question that the efficient operation of a refuse collection service demands the driving energy of a practical man. In the larger cities there should be available the services of a trained engineer to gage the unit cost of the work and its efficiency and to make changes in district and route boundaries from time to time, as these become advisable from the standpoint of economy.

Recently we have heard a great deal regarding technological unemployment and a shorter working day. Weeks ago industry signed the President's Unemployment Agreement, called the "blanket code," but our municipalities in general have not joined the NRA. If we look back a generation we will find that our municipalities and government services in general have been the leaders in shortening working hours, and that industry has followed along behind, but has come into step after some delay.

In some cities the refuse collection service offers an example in regard to the use of a shorter working day in municipal activities. For many years in cities where the 8-hour day is required by law it has been rather common practice to divide the work of the city among the collection crews so that each crew has its daily stint. In stormy weather and during peak seasons each crew is required to clean up its district, regardless of the number of hours demanded, without additional compensation for any overtime which might be required. This is offset, however, by

the practice of placing the men "on their own" and releasing them when the work is done. In this way it has been found that in some of our better organized collection services the men frequently finish a reasonable 8-hour day's work in considerably less than 8 hours. The dispatch with which the men work under these conditions, always assuming that thoroughness is insisted upon, brings about a better service at no additional cost to the tax payer.

In conclusion, the answer to the question asked in the title is "Yes." Refuse collection and disposal systems can be improved by placing the work in the hands of practical men and engineers; by taking the operation away from our boards of health, doctors and laymen, but leaving the privilege of making complaints against poor service to the boards of health; by making engineering studies of the work done by units of cost and work accomplished, rather than by comparing the work of one city with that of another.

The operating services of our municipalities can be improved and at the same time provide an outlet for the increasing number of graduates from our universities by diverting them from the construction or producing field into the operating or consuming field. If the country has reached the point economically where new construction or additional productive units are required to a lesser degree than in the past, some outlet such as this will be required for many of these technical men. A great hope for improvement in these systems lies in utilizing their trained services.

Examining Dairy Products for Members of the Escherichia-Aerobacter Group*

M. H. MCCRADY, F.A.P.H.A., AND J. ARCHAMBAULT

Division of Laboratories, Provincial Bureau of Health, Montreal, Que.

A REVIVAL of interest in the significance of the presence of organisms of the Escherichia-Aerobacter group in several dairy products, has resulted in the proposal of a variety of methods for the detection and enumeration of these organisms. The solid media, such as Endo, bile salt and eosin-methylene-blue agars, and the liquid fermentation-tube media such as lactose broth, gentian violet bile, and brilliant-green bile, all appear to have their proponents. Unfortunately, little detailed information regarding the comparative value of these various media is available; and a recent survey of the methods and media presently used in laboratories and milk plants suggests that sufficient consideration is not always accorded certain essential requirements of the application of the routine colon test to such products. Our purpose is to discuss briefly some of the more important of these requirements and to detail the results obtained from a limited comparison of various methods of estimating the number of Escherichia-Aerobacter in milk.

It should be observed, at the outset, that the particular numerical range requirements of a colon test to be applied to a given product may at once eliminate from consideration certain media and certain methods. For example, evidence is accumulating that the num-

ber of colon organisms in properly pasteurized milk should be very low—not more than 10 or 20 per 100 c.c.—and the method of estimation employed should be adapted to numbers of this order of magnitude. This requirement immediately eliminates the possibility of using, practicably, any of the common plate media, since not more than 0.1 to 0.01 c.c. of milk can be plated in agar in the usual 100 mm. Petri dish. One colony on such a plate poured with 0.1 c.c. of sample is equivalent to 1,000 organisms per 100 c.c., whereas the laboratory is here interested in densities as low as 10 or less per 100 c.c. There is no doubt that the practice of plating comparatively infinitesimal portions of pasteurized milk for detection of colon organisms has served to delay desired progress in the control of pasteurization, for negative results with such plates have engendered a false sense of security on the part of those entrusted with the control. The use of fermentation-tubes and liquid media appears, at present, to be the only practical method for work of this character.

Another consideration which deserves special attention when applying a colon test to a given product is the quantitative possibilities of the method. As soon as the question of *number* of organisms enters the field, the equally important question of *precision* of the result obtained demands recognition. The error of simple

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

sampling, to which all the usual methods of examination are subject, is so great that particular care must be exercised to choose a method which will yield fairly reliable results. It is perhaps not generally realized that, because of the chance distribution of the few colon organisms in the sample or dilution, no method commonly employed at present of which the authors are aware will yield results which are, with any fair degree of assurance, within 50 per cent of the true value.

This fact is brought out in Table I, which shows, approximately, the relative precisions obtainable from certain plate and fermentation-tube systems of examination. It is assumed that reasonable assurance is provided by odds of about 32 to 1, and the precisions were calculated by means of available formulae¹ on this basis. The precisions of various results obtained even from the same system may vary somewhat, so the figures given must be considered as merely rough approximations. It is to be noted that these precisions hold only when all conditions are favorable: dilutions properly chosen, samples and dilutions well shaken, and the simple error of sampling the only cause of error operating.

fully warranted, in view of the promise of convenience and precision of results which the plate method offers.

As the number of organisms in the sample becomes less than about 5 per unit of quantity plated, however, the precision of the plate count falls off rapidly, and completely negative plates become numerous. Two requirements of a plate method are, therefore: (1) It should preferably yield a count of 5 or more countable *Escherichia-Aerobacter* colonies, and (2) it should be so selective that these colonies may be fairly surely recognized.

On the other hand, even a moderately precise fermentation-tube method must include the use of at least 5 tubes with each dilution of sample. A larger number of tubes must be used if the precision of the result is to exceed that represented by the range of about one-third to four times the actual number of colon organisms present.

A third essential to reasonable accuracy in estimating the density of colon organisms in dairy products is the practice of duplicating the tests. It may seem unnecessary to stress the importance of checks in any bacteriological work, but the physical characteristics of many dairy products and the facili-

TABLE I
RELATIVE PRECISION OF RESULTS

System of Examination								<i>Odds are 32 to 1 that the most probable numbers obtained will fall within the range of approximately</i>							
2 tubes with each of 3 or more dilutions								30 to 1,000	per	cent	of	true	number		
5 " " " " 2 " " "								30 to 400	"	"	"	"	"	"	
10 " " " " 1 " " "								40 to 250	"	"	"	"	"	"	
Plate counts, when count is 5 to 10								20 to 200	"	"	"	"	"	"	
" " " " " 10 to 50								60 to 150	"	"	"	"	"	"	
" " " " " 50 to 100								75 to 120	"	"	"	"	"	"	

It is interesting to observe that one plate count of, say, 8 colonies is a result quite as reliable as that obtained from 10 fermentation-tubes. The numerous efforts directed toward the development of selective plate methods are evidently

ties for local, undistributed multiplication of bacteria which they offer render representative sampling a problem. Those familiar with milk-slide microscopic work appreciate the difficulty of sampling due to the frequent presence

TABLE II

COMPARATIVE COUNTS OF COLON ORGANISMS ON SOLID MEDIA *

Sample No.	Bile Salt	Endo	EMB
59	16	22	20
60	crowded	crowded	crowded
61	310	310	300
62	18	18	8
63	33	39	122 (32 + 90?)

* Counts given are the sum of the counts from 2 plates.

of masses of colon organisms which may be broken up by manipulation, such as that of pipetting. In consequence, the practice of relying upon the results from 1 plate only, or from 1 tube with 1 or more dilutions is not to be recommended. The use of several fermentation-tubes with each dilution provides an automatic check on the results; when the plate method is employed at least 2 plates should be prepared to provide a similar check.

PLATES VS. FERMENTATION-TUBES

Plate Methods—Plates and solid media offer certain advantages, as compared with fermentation-tubes, in the estimation of the number of colon organisms in dairy products, particularly when the sample contains a comparatively large number of these organisms. The advantage in precision of results obtained from the plate method has already been pointed out. Provided a readily prepared and really selective plate medium were available, the plating procedure would frequently be the method of choice.

The lack of selectivity of the solid media more commonly used for this purpose, however, constitutes a source of error which requires careful consideration when plates are employed. Kline,² for example, reports:

We have found another type of bacteria giving more or less typical "colon" reactions on Endo's media—an organism that gives a good "colon" reaction on the media, but does not possess the ability to ferment sugars with the production of gas, producing only

acid. . . . Sometimes these acid-forming but non-gas-producing organisms appear in quite large numbers as shown in Table VI covering a special study of six pasteurizing plants.

TABLE VI (in part) FROM KLINE

	Raw	Pasteurized
Samples	88	95
Cultures	260	65
Gas formers	174	25
Acid formers	86	40

It will be noticed that about half of the cultures examined by Kline in this special study failed to produce gas and therefore failed to conform to the usual definition of *Escherichia-Aerobacter* organisms.

Similarly, the authors, in a study of raw milks by the plate methods, found a great variation in the proportion of typical colonies which proved to be colon organisms when different samples were examined. The media employed were a special bile salt agar, Endo, and eosin-methylene-blue agar. The samples represented raw milks supplied by different dealers; 2 plates of each medium with 0.01 c.c. of sample in each, were poured. The results from a series of consecutive samples are shown in Table II.

It will be observed that the counts of typical colonies in the 3 media check fairly well. A number of colonies were fished from each plate into lactose broth; if gas appeared, a streak was made on eosin-methylene-blue agar and resulting growth completely confirmed

by the *Standard Methods of Water Analysis* of the A.P.H.A. Table III shows the results of this procedure.

attempted to use eosin-methylene-blue and several other agars in this way for examination of water, but with indif-

* Denominator indicates number of colonies examined.
Numerator indicates number of colonies confirmed.

The colonies from samples Nos. 62 and 63 were similar to the majority of those from the other samples, yet not one of the 38 colonies fished from these 2 samples proved to be *Escherichia-Aerobacter*. Only 33 per cent of all the typical colonies from the 5 samples were confirmed as colon organisms. Other series of samples examined in the same manner, but employing only Endo agar, yielded similar results.

Evidently the so-called "typical colon colonies" appearing in these solid agar pour plates should not too hastily be accepted as colonies of *Escherichia-Aerobacter*. Since the proportion of such colonies proving to be of colon organisms will vary with different samples, it is essential that a number of the colonies from each sample be actually confirmed before the count can be taken as an indication of the number of *Escherichia-Aerobacter* contained in the sample.

A departure from the pour-plate method, involving the spreading over the surface of a dried agar plate a small quantity of sample and then again drying the plate before incubation, has been employed by some workers. The authors have no data to offer concerning the value of this method in milk examination. Some years ago they

ferent results because of the difficulty of recognizing *Escherichia-Aerobacter* colonies.

Fermentation-tube Methods—Many different media have been employed in fermentation-tubes for the estimation of the coli content of milk and other dairy products. Although published reports of comparative work with various media are few, there seems to be a consensus of opinion that ordinary plain lactose broth is unsuitable for this purpose. The experience of the authors with lactose broth for detection of colon organisms in milk has been very disappointing. Kessler and Swenarton³ reported that they tried and discarded plain lactose broth, and suggested that the failure of this medium was probably due to inhibition of colon organisms by the acidity rapidly produced by other types of bacteria present. They proposed a gentian violet-lactose-peptone bile for the test. With this medium over 99 per cent of positive presumptives (gas in 48 hrs. at 37° C.) were "partially confirmed," by production of typical colonies on eosin-methylene-blue agar streaked with material from the presumptive tube.

The authors have conducted a limited series of tests for the purpose of comparing gentian-violet bile with

brilliant-green bile 2 per cent Special, a medium commonly employed for water examination. It was thought that many laboratories might find it convenient to use the same medium for water and for milk. A total of 139 samples of bottled pasteurized milk was tested by placing each of 4 dilutions (1 c.c., 0.1 c.c., etc.) of the sample in 2 tubes of each medium and incubating at 37° C. for 48 hours. The results are given in Table IV. Of the 139 samples, 55 contributed one or more positives; in no instance were all the tubes planted from one sample positive.

almost a sure indication of the presence of colon group organisms. Since 86 per cent of the tubes with at least 10 per cent gas, when pasteurized milk was examined, were completely confirmed as colon group organisms, the production of gas in that amount may reasonably be considered an indication of the presence of these bacteria in routine work. Indeed, in pasteurization control, the experience of the authors indicates that gas in any amount is seldom formed from 10 ml. samples taken at the pasteurizer (when properly operated) and that, in consequence, any

TABLE IV
COMPARISON OF GENTIAN VIOLET BILE AND BRILLIANT GREEN BILE

Portions of milks tested	1 c.c.	0.1 c.c.	0.01 c.c.	0.001 c.c.
10% or more gas, 48 hrs.				
Tubes of gentian violet bile	51	31	22	8
Tubes of brilliant-green bile	61	39	23	9
Gas, but less than 10%, 48 hrs.				
Tubes of gentian violet bile	6	3	2	2
Tubes of brilliant-green bile	10	3	0	1

The results agree fairly closely, the brilliant-green bile yielding a somewhat larger number of positive presumptives, particularly with the lower dilutions. The more frequent failure of lower dilutions to yield gas in gentian bile when higher dilutions yielded gas accounted, in large part, for the fewer positives with this medium.

The series of comparative presumptives described above were not confirmed, but later another series of positive presumptive tubes of brilliant-green bile were confirmed with the results shown in Table V. The system of examination employed was that of planting 2 to 5 tubes with each of 4 dilutions, 1 c.c., 0.1 c.c., etc. All tubes with gas were subjected to the confirmation procedure.

It is evident from the results shown in Table V that when raw milk was tested in the manner described any amount of gas formed in the tube was

gas found in the majority of tubes containing such quantities of pasteurized milk usually indicates some fault in the processing of the milk.

It may be of interest to note that, in the course of the confirmation of the presumptives described above, the number of confirmations was increased by 11.5 per cent by fishing a second colony from the eosin-methylene-blue plate. Approximately the same proportional increase was obtained from raw as from pasteurized samples.

A recent tendency, here and abroad, is toward more rigid requirements, as regards colon group density, for pasteurized milk. In order to determine the practicability of testing quantities of milk larger than 1 c.c., a series of milk and cream samples (all pasteurized) were examined by planting two 10 c.c. quantities in brilliant-green bile tubes, the medium being of the special strength usually employed for 10 c.c.

TABLE V

RESULTS OF CONFIRMATION OF POSITIVE BRILLIANT-GREEN BILE PRESUMPTIVES

Pasteurized Milk: 54 samples (with positive presumptives) from
29 different pasteurized supplies.

	<i>10 Per Cent or More Gas in 48 Hrs.</i>	<i>Less than 10 Per Cent Gas in 48 Hrs.</i>
Number of presumptives	153	51
Number completely confirmed	132	23
Proportion completely confirmed	86%	45%

Raw Milk: 25 samples (with positive presumptives) from
20 different raw milk supplies.

Number presumptives	112	12
Number completely confirmed	111	11
Proportion completely confirmed	99%	92%

quantities of water (20 c.c. of medium in the tube; 60 gm. of dehydrated medium per liter). A total of 100 tubes from 53 different samples showing at least 10 per cent of gas after incubation for 48 hrs. at 37° C. were subjected to the completed confirmation procedure. Every one of these 100 tubes was confirmed as containing colon group organisms. Apparently 10 c.c. quantities of sample can be tested by means of brilliant-green bile with reasonable assurance that the formation of at least 10 per cent of gas in the fermentation-tube indicates the presence of organisms of this group.

The results here recorded indicate that brilliant-green bile constitutes a satisfactory medium for the routine estimation of the number of colon group organisms in milk. Although the number of presumptives examined was not large, they were obtained from a series of many hundreds of samples which were taken from many different milk supplies in various cities and towns and which were fairly representative of the general milk supply of the Province of Quebec. The representative character of these samples compensates, in some measure, for the limited number examined.

SUMMARY

The great variation in the numbers of *Escherichia-Aerobacter* organisms which may be found in milk and other dairy products necessitates careful discrimination in the choice of the routine method of estimation which is best adapted to the examination of the particular product under consideration. Three requirements which deserve special notice are:

1. The necessity of choosing a method which will permit enumeration in the range of numbers of organisms to be found in the sample. There is little advantage in testing 0.1 ml. of pasteurized milk by means of a plate method when such milk usually contains only a few colon organisms in 100 ml. of sample.
2. The necessity of choosing a method which will yield results of the desired precision. The error of simple sampling is such that, when the dilution-tube system is employed for routine work, at least 5 tubes should be planted with each dilution. It is pointed out that the count on a single satisfactorily differential plate with from 5 to 10 recognizable colon colonies is quite as precise as the result from 10 fermentation-tubes planted with the proper dilution of the sample. The search for differential plate methods for enumerating colon organisms is well warranted.
3. Whether plates or tubes are used, duplicates are advisable in order to detect gross errors in the results obtained.

Comparative results obtained from examination of milk samples for *Escherichia-Aerobacter* by various methods suggest the following tentative conclusions:

1. So-called "typical" colonies appearing in solid media pour-plates inoculated with milk may not be accepted as colonies of *Escherichia-Aerobacter* unless a sufficiently thorough examination of a large number of colonies from representative samples has proved that they may be so accepted. In the hands of the authors plates poured with neither Endo, bile salt, nor eosin-methylene-blue agar proved reliable for direct enumeration of colon organisms in milk samples, since the proportion of resulting typical colonies which were confirmed varied from zero in some samples to 100 per cent in others. It is quite probable that similar difficulties would be encountered in the examination of dairy products other than milk by these plate methods.

2. The production of 10 per cent or more gas in brilliant-green bile 2 per cent special fermentation-tubes inoculated with quantities of raw or pasteurized milk varying from 10 c.c. to 0.001 c.c. and incubated 48 hrs. at 37° C. provides reasonable assurance of the presence of *Escherichia-Aerobacter* organisms. This medium appears to be as reliable as gentian violet bile for the enumeration of these organisms, and is more conveniently em-

ployed in those laboratories where it is also used for examination of water samples. The percentage of such brilliant-green bile presumptives which were completely confirmed varied as follows:

Raw milk, 1 c.c. to 0.001 c.c.	99%
Pasteurized milk, 10 c.c.	100%
Pasteurized milk, 1 c.c. to 0.001 c.c.	86%

It is pointed out that since the organisms in 10 c.c. of properly pasteurized milk rarely produce gas in this medium, the production of any amount of gas from the majority of such samples of 10 c.c. or less of a pasteurized milk is usually indicative of some fault in the processing of the milk, either improper pasteurization or recontamination of the pasteurized product.

Mother's Day—May 13

THE Maternity Center Association of New York announces its annual Mother's Day Campaign, and that Mother's Day this year is to be observed May 13. Those interested in

securing aid for local groups who wish to lower maternity mortality in their own communities may apply to Mrs. Shepard Krech, President, 1 East 57th Street, New York, N. Y.

Epidemiology of Lobar Pneumonia*

WILSON G. SMILLIE, M.D., F.A.P.H.A., AND
FREDERICK S. LEEDER, M.D.

*Professor of Public Health Administration, and Research Epidemiologist,
School of Public Health, Harvard University, Boston, Mass.*

IN a preliminary study one of us¹ determined the prevalence of various types of pneumococci in the nasopharynges of persons who had been in intimate contact with cases of lobar pneumonia. Nasopharyngeal cultures of over 1,000 persons (contacts and controls) indicated that Types I and II pneumococci were much more prevalent in the nasopharynges of immediate family contacts of cases of lobar pneumonia due to the homologous organisms than in the population at large. This suggested the advisability of further study in an attempt to determine the significance of this finding. Does the case of lobar pneumonia due to Type I or II pneumococcus infect his immediate contacts; or do these types invade the nasopharynges of a family, establish themselves and ultimately produce pneumonia in one unfortunate member? An answer to at least a part of this question might be reached by first taking cultures of the family contacts of an individual who had developed lobar pneumonia. One would then remove that person to a new uninfected environment, thus exposing a new, presumably susceptible and uninfected group of contacts, and make a study of this new group. Our approach to the problem was to restrict ourselves to a study of the contacts of cases of lobar pneu-

monia which were due to Type I or II pneumococcus and that were taken to the wards of general hospitals early in the course of the disease. We compared the nasopharyngeal content of the home contacts of each case with the nasopharyngeal content of hospital contacts of the same case.

The hospitals of Metropolitan Boston coöperated in the study and informed us immediately by telephone whenever a case of lobar pneumonia due to either Type I or Type II pneumococcus was admitted to their wards. Our procedure was to culture immediately the new environment of the patient; namely, the hospital patients adjoining the new case (if the case was in a large ward), or all the contacts, if the new case was placed in a small 4- or 5-bed ward. This enabled us to establish the nasopharyngeal flora present in the new environment at the time of the introduction of a source of Type I or II pneumococcus. These contacts were then re-cultured at intervals as long as the contact remained unbroken, and as long as the pneumonia patient continued to exhibit Type I or II pneumococci in his sputum.

The environment from which the patient had come was studied concurrently. The family from which the case had been removed was visited, and nasopharyngeal cultures were taken from as many of the immediate family contacts as possible.

As a further index of the extent to which Type I or II pneumococcus

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

TABLE I

NASOPHARYNGEAL CULTURES ON HOSPITAL PATIENT AND FAMILY CONTACTS OF CASES OF LOBAR PNEUMONIA DUE TO TYPE I PNEUMOCOCCI

	Cases	Contacts	Contact Days	Negative	Positive and not Homologous	Positive and Homologous	Per Cent Positive and Homologous

Contacts	20	61	426	38	50	1	1.6
Family							
Contacts	17	62	153	13	34	15	24.2

strains are transmitted from acute cases to their contacts, house officers, nurses, and orderlies working on the wards in which lobar pneumonia caused by these types of pneumococcus were being treated were cultured. These cultures were taken before exposure to the case, during exposure, and at intervals after the exposure had ended.

Several families in which the incidence of homologous carriers was high were cultured at regular intervals to discover the length of time a "healthy" carrier was likely to carry a Type I or II pneumococcus.

Various factors of the environment which might influence the transfer of pneumococci from patient to contact, such as overcrowding, low economic or social status, were noted. Similarly, variations in the individual contacts, such as age, the existence of respiratory disease, or the occurrence of acute respiratory infection, chilling of the body by exposure, etc., received attention.

The pneumococci were identified by

standard mouse passage and tube agglutination technic as recommended by Cooper² whose specific sera from I to XXXII, inclusive, were employed. Our Type XX serum cross-agglutinated with so many types of pneumococci that it was used only occasionally, which probably accounts for our finding this type but once. The virulence to a mouse of each strain of pneumococcus that was isolated from a contact was determined. The technic and personnel for both this study and the one previously reported by Smillie¹ were the same, so that the results of the two are comparable.

The general study was continued through a 9 months period, November to July, inclusive.

FAMILY, PATIENT, AND HOSPITAL STAFF CONTACTS OF LOBAR PNEUMONIA DUE TO TYPE I OR II PNEUMOCOCCUS

The contacts of 64 cases were studied. Of these 64 cases, Type I was the infecting organism 42 times, and Type II, 22 times.

Hospital Staff Contacts

*Indicates the presence of a cold at the time the culture was taken.
H.O. indicates House Officer
N. indicates Nurse.

Family contacts were considered only when they had been in contact with the patient within 7 days; and hospital patients were cultured only if they occupied contiguous beds in a large ward or were in a small 4- or 5-bed ward with the case. Thus, all contacts could be called intimate from the point of view of ease of exchange of nasopharyngeal flora by droplets.

The distribution of cases and contacts was: 61 patient contacts of 20 Type I cases; 62 family contacts of 17 Type I cases; 33 patient contacts of 11 Type II cases; 37 family contacts of 10 Type

II cases; and 71 hospital staff contacts of 5 Type I and 1 Type II cases.

A summary of the results of the study of these 5 groups is shown in Tables I, II, and III. Diagram I illustrates the details of a typical study on hospital staff contacts.

The striking thing about the tables is the high percentage of homologous carriers among the family contacts, as compared to the low percentage among hospital staff or patient contacts. This difference is further emphasized when we compare the number of contact days for family contacts with the number of

TABLE III

NASOPHARYNGEAL CULTURES ON HOSPITAL PATIENTS, HOSPITAL STAFF AND FAMILY CONTACTS OF CASES OF LOBAR PNEUMONIA DUE TO TYPE I OR II PNEUMOCOCCI

	Cases	Contacts	Contact Days	Negative	Positive and not Homologous	Positive and Homologous	Per Cent Positive and Homologous
Hospital Patient Contacts	31	94	707	63	75	2	2.1
Hospital Staff Contacts	6	71	610	42	27	2	2.8
Family Contacts	27	99	287	22	56	21	21.2

contact days for hospital staff and patient contacts. Sixty-two family contacts of 17 Type I cases were exposed for 153 days and yielded 15, or 24.2 per cent, homologous carriers, whereas 61 hospital patient contacts of 20 Type I cases were exposed for 426 days and yielded only 1, or 1.6 per cent, homologous carriers. A similar relationship exists for contacts of Type II cases. Thirty-seven family contacts of 10 Type II cases yielded 6, or 16.2 per cent, homologous carriers for 134 days exposure, whereas 33 hospital patient contacts of 11 Type II cases yielded only 1, or 3.0 per cent, homologous carriers after 281 contact days. Similarly, 71 hospital staff contacts of 5 Type I and 1 Type II cases yielded only 2, or 2.8 per cent, homologous carriers after 610 days of exposure.

Another striking thing in relation to family contacts should be emphasized, namely, that one is just as likely to find homologous carriers among the family contacts of cases of Type I or II lobar pneumonia on the first day of exposure as after a week of exposure. That is, the number of contact days following the onset of the lobar pneumonia does not appear to affect the carrier rate in the home. This, coupled with the low rate of spread in hospitals, suggests that there must be some additional factor which determines whether or

not a Type I or II pneumococcus becomes established in the nasopharynx of persons that are exposed to cases of lobar pneumonia due to these particular strains.

In order to study this phenomenon further, we determined to introduce a known healthy carrier of Type I pneumococcus into a group of normal persons that were free from pneumococci of this particular type, and then to measure the spread of the organism in the new, uninfected environment, incident with the culturing of a group of controls in the Wrentham State School for Mental Defectives, we discovered that an inmate, E. H., age 28, harbored a strain of virulent Type I pneumococcus in her nasopharynx. E. H. gave no history of previous pneumonia, nor of contact with a case. E. H. was in Building F, housing a group of slightly mentally retarded females, averaging about 25 years of age, so that the group was fairly similar to one of normal adults. On the campus was another building—B—with a comparable group of women at a slightly higher age level, averaging about 30 years of age. Each building was a unit, with little contact from building to building, or with the outside.

The plan followed was to culture first the occupants of Building F, in

which E. H. had been a patient for several years. We also cultured the occupants of Building B in order to establish the normal nasopharyngeal flora of the persons in the two buildings. We then transferred E. H. to Building B and cultured, at frequent intervals, her new contacts in this new environment.

Building F contained 116 girls. They were about equally divided between 3 wards in which the beds were arranged as elsewhere in the institution; the head of one touching the foot of the next one, and the rows separated by a narrow aisle just wide enough to allow a person to walk between the rows. The night time contact, therefore, could be considered closer than would be found either in the home or in a gen-

eral hospital. Building B housed 97 girls under exactly the same living conditions, so that the degree of contact in the two buildings was comparable.

The two buildings gave a total of 213 persons. Of these 103 (48.3 per cent) harbored pneumococci of various types, and 110 (51.7 per cent) did not. These percentages are compatible with the figures obtained by other workers for the normal population. Gundel,³ in 1,114 cultures of school children, found 734 strains of pneumococci, and Smillie,¹ in 458 cultures of a cross-section of the normal population, found 212 strains. In our series of cultures from Building B and F, all of the 32 Cooper types except II, XXII, XXIII, XXVI, XXVII, XXIX, XXXI, and XXXII were recovered. Types III,

TABLE IV

Contacts in contiguous beds, but not at same dining table	11	—	—	Neg.	*	III	—	Neg.	Neg.

* Type I carrier introduced on this date

VII, X, and XVIII were found most frequently, but no single type predominated. Type I was not found in Building B. In Building F, where the carrier was an inmate, 2 other girls yielded Type I pneumococcus on one occasion. It was impossible to obtain this organism from these 2 inmates on repeat cultures. Only E. H. was continually positive for the virulent Type I pneumococcus.

The culturing of the two buildings was started on June 28, and was completed on July 19, on which date E. H. was transferred from Building F to Building B, and her new contacts were then cultured at intervals. Our procedure by days follows:

- July 21—Contacts in contiguous beds—Building B
- July 21—Previous contacts in contagious beds—Building F
- July 24—Contacts at same dining table—Building B
- July 26—Contacts in same ward, but not in contiguous beds—Building B
- July 26—Contacts in same building, but not in same ward—Building B
- July 26—Previous contacts not in same ward—Building F
- July 27—Contacts in same building, but not in same ward—Building B
- July 27—Contacts in contiguous beds—Building B
- July 28—Contacts at same dining table—Building B
- July 28—Contacts in contiguous beds—Building B

It will be noted that we concentrated our efforts on contacts occupying beds contiguous to E. H. and to contacts eating at the same dining table. Many of the people in the contiguous beds also used the same dining table, so that some had more contact than others. As a check, cultures were also taken from time to time in the other wards in Building B and in Building F from which E. H. had come. None of these control cultures were positive for Type I pneumococcus.

The results of one group of serial

cultures of intimate contacts of E. H. in her new environment are shown in Table IV. It is obvious from this table that E. H. did not infect her new contacts with Type I pneumococcus, though she continued to carry this strain throughout her stay in Building B.

Analysis of all the data, consisting of approximately 125 nasopharyngeal cultures of immediate contacts, reveals that the introduction of an individual harboring Type I pneumococci in the nasopharynx into a group of people having continued close contact with the carrier was without effect. This statement, however, is modified by the length of contact, which was fairly short, July 19–28; and by the time of the year, July—a month during which the incidence of pneumococci in the population is low, and in which little lobar pneumonia occurs. Additional important data would be secured if one repeated the Wrentham experiment during the winter months, or during an outbreak of upper respiratory disease, such as the common cold.

We have some evidence that Type I pneumococci, under certain conditions, may be transmitted through contact in the hospital. In one instance of close contact of a hospital staff member with an infected person, it would appear that a strain of Type I pneumococcus was transmitted from patient to contact and that lobar pneumonia due to Type I pneumococcus had resulted.

On March 9, a girl $2\frac{1}{2}$ years old, suffering from lobar pneumonia, complicated by an empyema, was hospitalized, and Type I pneumococci were isolated from the nasopharynx, and from the pleural fluid. We made serial nasopharyngeal cultures on 7 doctors and 3 nurses who came in contact with this child. On March 20, Dr. A., who was in charge of aspirating pus from the pleural cavity, developed lobar pneumonia due to Type I pneumococcus.

Dr. B. assumed care of the child, and on March 25 a nasopharyngeal culture of his throat revealed Type I pneumococcus, but he did not develop pneumonia. The remaining 5 doctors and 3 nurses were cultured repeatedly until April 11, on which date the case ceased to exhibit Type I organisms. None of them became positive for Type I pneumococcus.

Since this child was the only known source of Type I pneumococcus in the hospital, it would seem reasonable to assume that this patient was responsible for the spread of the infection to the 2 doctors, the spread probably being influenced by the intimate contact as-

sociated with the aspiration of the pleural cavity of a small child.

Several families in which there occurred a high percentage of contacts that carried Type I or II pneumococci were studied with special care.

Family A—The mother of Family A became ill on January 14 with lobar pneumonia. The infecting organism was Type II pneumococcus. On the following day a small daughter developed lobar pneumonia, also caused by a Type II pneumococcus. Both patients were removed to a local hospital on January 15. On January 17, the 6 remaining members of the family, 1 man, 2 boys, and 3 girls, were cul-

DIAGRAM 2

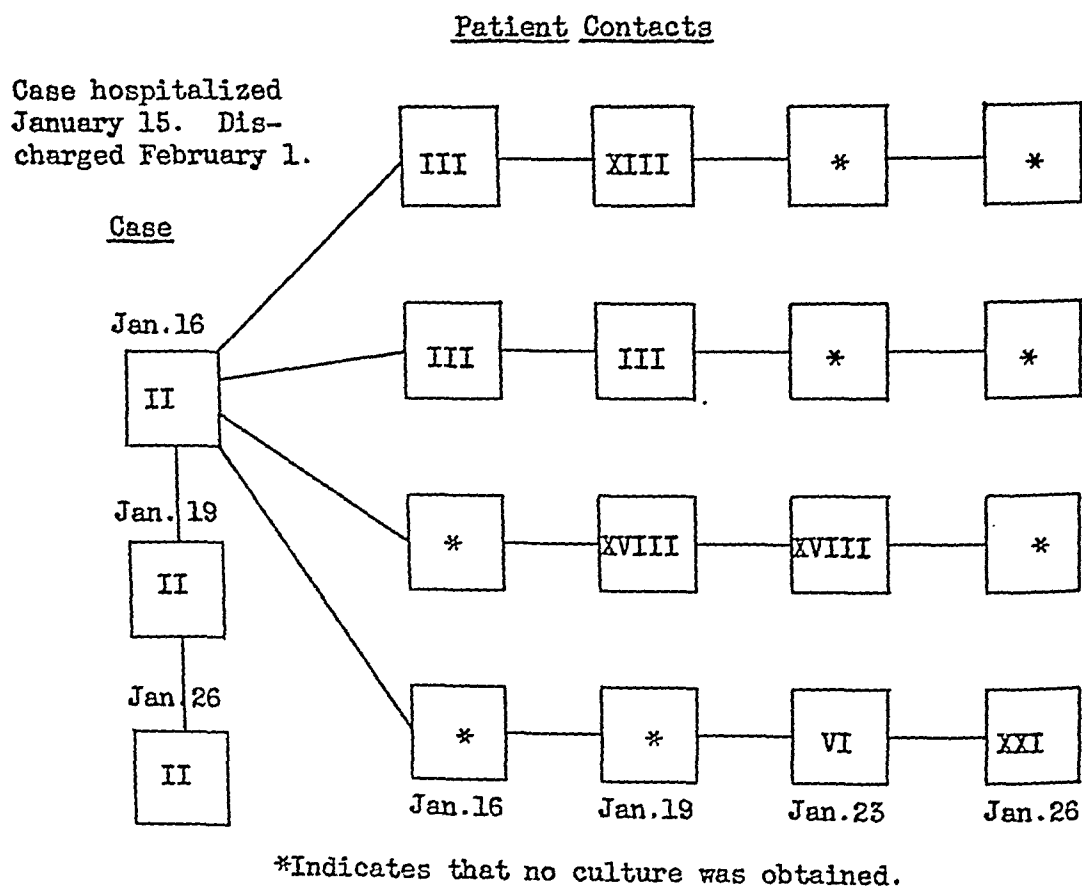

PNEUMOCOCCI ISOLATED FROM THE NASOPHARYNGES OF SIX MEMBERS OF A FAMILY IN WHICH TWO CASES OF TYPE II LOBAR PNEUMONIA OCCURRED

DIAGRAM 3

PNEUMOCOCCI ISOLATED FROM THE NASOPHARYNGES OF FOUR PATIENTS OCCUPYING THE SAME FIVE-BED WARD AS A CASE OF TYPE II LOBAR PNEUMONIA

tured. Type II pneumococci were recovered from the nasopharynges of 4 of these contacts. Two that carried Type II pneumococci had had colds at the time the cultures were taken, and 2 had not had bad colds for more than a month.

These 6 contacts were recultured at about 2-week intervals until 5 serial cultures had been obtained (Diagram II). It will be noted from the diagram that 1 continued positive for Type II pneumococcus throughout; 1 yielded Type II pneumococcus only on the first culture; 1 yielded Type II on the second culture, became negative to Type II, and finally exhibited a Type III;

and 1 yielded a Type II on the second and last cultures, having been negative for Type II in the meantime.

The 2 patients who had been in the hospital with pneumonia returned home on February 1, free from Type II pneumococcus. The mother remained consistently negative, but her daughter became positive for Type II pneumococcus again, after being negative for this strain on two previous cultures. It is interesting to note that during the 2½ months that the family was studied it was never free from a source of Type II pneumococcus, and that the 2 persons who became negative to Type II pneumococcus and later positive both

gave a history of an acute cold at the time the Type II pneumococcus was recovered.

The mother of Family A was hospitalized in a 5-bed ward and serial cultures were taken on the 4 patients in her new environment. These having on the average at least 4 days close contact with her, each failed to yield a Type II pneumococcus (Diagram 3).

Family B—On January 23, the mother of Family B developed lobar pneumonia due to Type I pneumococcus. On January 27, 4 days after the patient had been removed to a hospital, nasopharyngeal cultures were taken on 10 home contacts, 6 of whom were found to be carrying Type I pneumococci. In this particular family, 9 of the 10 contacts, which included all 6 of the homologous carriers, had severe colds at the time the cultures were taken (Diagram 4). This family was not followed at short intervals, but

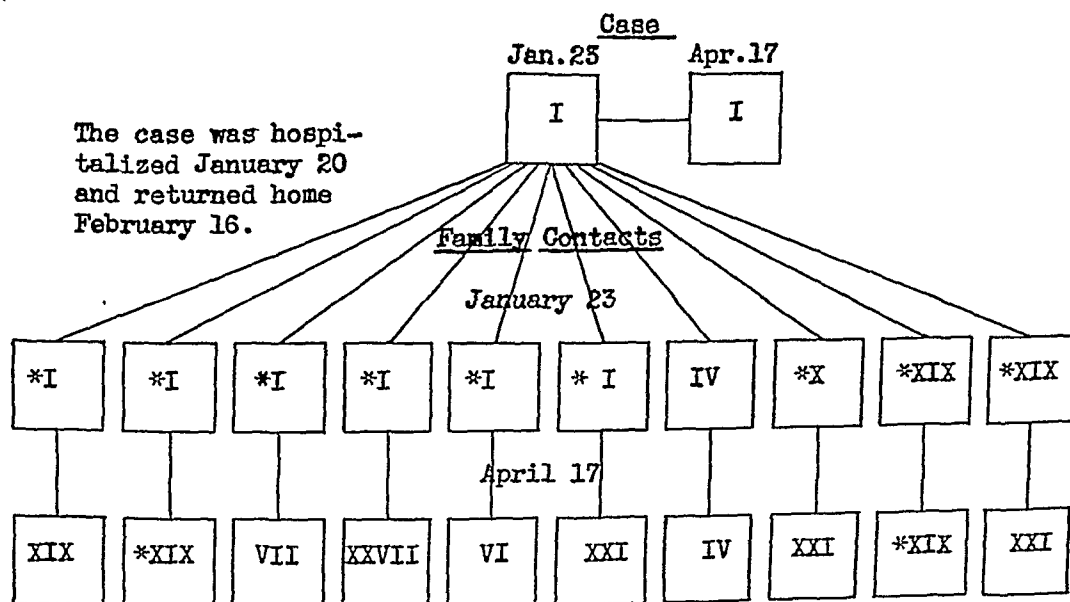

when recultured April 17, nearly 3 months later, none of the contacts yielded Type I pneumococci. The original case, however, who had recovered and returned home February 16, was still positive for Type I pneumococcus on April 17.

The mother of Family B was hospitalized in a 5-bed ward and serial cultures were taken on the 4 patients in her new environment. As with Family A, the 4 patients, having at least 4 days close contact with her, each failed to yield a Type I pneumococcus.

Family C—In April, 1932, a 13 year old boy in Family C developed lobar pneumonia due to Type II pneumococcus. Five family contacts that were cultured at the time yielded 4 type II carriers. This family was not followed at frequent intervals, but the hospital records show that the child developed a chronic empyema, from which Type II pneumococci were recovered, and which

DIAGRAM 4

*Indicates the presence of a cold at the time the culture was taken.

continued to discharge for several months after the child returned home. The family was recultured in April, 1933, nearly a year later, and Type II pneumococci were recovered from the nasopharynges of the original case and 3 of the 4 original carriers.

THE RELATIONSHIP OF ACUTE RESPIRATORY DISEASE IN CONTACTS OF TYPE I OR II LOBAR PNEUMONIA TO PREVALENCE OF PNEUMOCOCCI IN THE NASOPHARYNX

It has been suggested that a person with a cold is more likely to harbor pneumococci than one without a cold. Our data indicate, however, that pneumococci were not significantly more prevalent in contacts suffering from colds than in those free from colds. A different picture was presented when we considered only the group of contacts of Type I or II cases which harbored the homologous organism. Of our group of 25 homologous carriers, 19, or 76 per cent, had colds at the time they were cultured. The numbers are small, but the figures are significant, and suggest further study in this direction.

Our data indicate that overcrowded living conditions in the home, and also low economic status were not factors in the establishment of carriers of Type I and Type II pneumococci.

SUMMARY AND CONCLUSIONS

1. Nasopharyngeal cultures from 264 contacts of 64 cases of lobar pneumonia due to

Type I and Type II pneumococcus have been studied. The results indicate that $20\pm$ per cent of the immediate family contacts of these patients harbored the homologous strain in their nasopharynges. The hospital contacts of the same patients, however, were seldom infected (about 2 per cent). These results suggest that it is quite justifiable to treat cases of lobar pneumonia due to Type I and Type II pneumococci in the open wards of our general hospitals.

2. One experiment indicates that a healthy carrier of Type I pneumococcus does not transmit this organism to immediate contacts, even though the individuals are living under overcrowded conditions.

3. Our evidence suggests that there is some additional factor other than simple contact which determines the transfer of Type I or II pneumococci from a patient with lobar pneumonia to contacts. Nineteen of the 25 family contacts of cases of lobar pneumonia due to Type I or Type II pneumococci that became homologous carriers were suffering from acute colds at the time the cultures were taken. Positive cultures were found as frequently on the first day of exposure as after a week. This evidence suggests that family epidemics of colds may be a factor which determines the transfer and establishment of Type I and Type II pneumococci from the infected to the uninfected.

4. Carriers of Type I and Type II pneumococci, when once established, may continue as carriers of these strains for a considerable period of time without giving rise to lobar pneumonia in the carrier or his contacts and without producing a second group of carriers.

DR. ROSENAU RECEIVES SEDGWICK MEMORIAL MEDAL

AT the Indianapolis Annual Meeting the Sedgwick Memorial Medal for distinguished service in public health was awarded to Milton J. Rosenau, M.D., of Harvard Medical School.

The presentation speech by Professor E. O. Jordan, Chairman of the Sedgwick Memorial Medal Committee, was as follows:

"It is my privilege, as Chairman of the Committee on the Sedgwick Memorial Medal, to announce the award of this medal for distinguished service in public health to Milton Joseph Rosenau of the Harvard Medical School. The award is made on the basis of Dr. Rosenau's long and fruitful career in the field of public health, for his remarkably successful 10-year administration of the Hygienic Laboratory of the U. S. Public Health Service where he carried out pioneer investigations on anaphylaxis, for his practical work on disinfectants and on the pasteurization of milk, for his numerous original contributions to bacteriology and epi-

Milton J. Rosenau, M.D.

demiology, for his wise and inspiring participation in coöperative research upon influenza, pneumonia, and poliomyelitis, and especially for the service he has

rendered public health workers throughout the world by his classic book, *Preventive Medicine*. This award is peculiarly appropriate since Dr. Rosenau and Professor Sedgwick were intimately associated in the organization and direction of the pioneer Harvard-Technology School of Public Health."

Dr. Rosenau has been a member of the American Public Health Association since 1909, and is a Charter Fellow.

CLEAN FOOD, CLEAN HANDS, CLEAN DISHES

THE recent outbreak of amebic dysentery, which has caused more than 20 deaths, and which has spread to more than 100 communities throughout the country during the past few months, points to a task demanding the serious attention of all health departments: that of eliminating insanitary practices in the dispensing of food and drinks.

Amebic dysentery¹ first broke out in a Chicago hotel, where it was traced to food handlers.² The disease spread rapidly to other food handlers and thence to guests of the hotel, many of whom were visiting the Century of Progress Exposition, and it was carried back to more than a hundred widely scattered communities.

This is one example of what can happen when purveyors of food and drinks are not required to uphold high standards of sanitation, and when there is inadequate medical examination and supervision.

It is well known that in most restaurants, soda fountains and other public eating places, the basic principles of sanitation are not generally observed. No food handler, without first washing his hands thoroughly with soap and water, should serve a customer. How many do it? No dish should be used for serving food or drinks without first being thoroughly cleansed "in a solution of soap or soda or suitable cleaning powder in hot water followed by a thorough rinsing or spraying or immersion in clean boiling water (212° F.) for a period of 1 minute, or in hot water of a temperature of not less than 180° F. at all times when used for purposes of sterilization, for a period of 2 minutes; by sterilization with live steam, or by some other equally effective method approved by the Department of Health."³ What proportion of utensils used in public eating places, especially soda fountains, are washed in this way?

About 92 per cent of all communicable diseases are transmitted through the mouth and nose. Surely there is no better place to break the chain of saliva-borne and food-borne infections than at eating and drinking places. Transmission of disease by food and drink dispensers will end when the public demands that all food and drinks be served by healthy attendants with clean hands, in clean dishes, and health departments take vigorous action to enforce sanitary codes.

Health departments can help more than any other agencies in educating the public to demand that sanitary laws be strictly obeyed. This demand must come from the public. It is because of public apathy that sanitary laws now on the books are not more generally enforced.

Years ago the public accepted the common drinking cup. We believed that unnecessary sickness and death was the result, but the public did not seem to care. The public did not understand; that was the real reason it tolerated this deadly disease carrier. When health departments convinced the public of the awful price of the common drinking cup, action was demanded for its abolishment.

However, the common drinking cup has never really been abolished. We still have it, though not in the same form as before. Now it is in the form of glasses, dishes, and tableware inadequately cleansed between servings. Go to almost any soda fountain, in any city; watch the attendant pluck a glass from the counter, swish it about hastily in a basin of muddy-looking tepid water, rinse it quickly in cold water, then use it to serve another customer.

That glass is worse than the common drinking cup! Its superficial washing has served only to bring it into contact with germs from many other glasses "washed" in the same water.

Influenza, the common cold, tuberculosis, pneumonia, scarlet fever, diphtheria, whooping cough, and Vincent's angina,⁴ are among the principal diseases that can be transmitted by unclean eating utensils. Pathogenic organisms are not removed by common methods of washing. After they are used and hand washed, more than 20 per cent of the organisms remain adhering to eating and drinking utensils.⁵

Clean food, clean hands, clean dishes: These three hold great hope for the control of saliva-borne infections.

To educate the public, to demand sanitary practices in the dispensing of food and drink in restaurants, soda fountains, and other public eating places, there has been organized in New York City The Committee for the Study and Promotion of the Sanitary Dispensing of Food and Drinks.

This committee is urging the public, in its own interest, to follow four courses of action when eating in public:

1. Decline dishes, cups or glasses that are obviously unclean.
2. Quietly protest to the management against all insanitary practices observed.
3. Commend the management of public eating places that uphold high sanitary standards.
4. Report by name and address to the Board of Health, all public eating and drinking places violating high sanitary standards.

Endorsement of the purposes of the committee has already been given by many leaders in civic, industrial and public health fields.

NOTE: Dr. Alec N. Thomson, Secretary of the Public Health Committee of the Medical Society, County of Kings, is chairman of the Committee. Homer N. Calver, former editor of this JOURNAL, is executive officer.

BOVINE TUBERCULOSIS IN THE BRITISH ISLES

DURING the last few years the inhabitants of the British Isles seem to have become thoroughly aroused over the danger of bovine tuberculosis to human health. Much of this is apparently due to the report of the People's League of Health in 1932, an organization which seems to have been brought into being by Miss Olga Nethersole, who got together a committee of which the leading English journals spoke in the highest terms. Their report was thorough and an eye opener. Since that time the general findings have been endorsed by Sir George Newman and given official sanction. This history is somewhat surprising in view of the fact that the question of bovine tuberculosis and its relation to human health was brought to the fore at the Congress on Tuberculosis held in London in 1901, following which the English Royal Commission on Tuberculosis, which has done such excellent work, was appointed.

The Germans appointed an Imperial Commission, which after struggling vainly to support Koch's contention as to the lack of danger to human health from bovine tuberculosis, finally agreed to pretty nearly everything which we now know to be true. While bacteriologists, doctors and veterinarians in England, the Scandinavian countries, France, and even in Germany, had held that bovine tuberculosis was a menace to human health, we must say emphatically that the first positive proof of this was given from the Laboratory of the State Live Stock Sanitary Board of Pennsylvania early in 1902, though at the London Congress alluded to a paper from the same laboratory was read on the subject and a verbal report given of many cases of human infection from bovine sources, all of which seems to have escaped the notice of the English writers, with one or two exceptions.

The latest exposition of the subject is given by Savage.¹ He reiterates what we have taught in America for many years; namely, that the bovine tubercle bacillus belongs to the same species as other forms of the germ, having acquired its peculiar characteristics, probably by residence in the bodies of cattle. He combats the statement, which is not much heard in America, that the bovine strain is less virulent for man than the human, and says correctly that many cases of generalized tuberculosis are due to the bovine strain.

Most striking are the figures calculated from the tables of the Registrar-General of England, showing that from 1920 to 1931 inclusive, there have been 25,166 human deaths in England due to the bovine tubercle bacillus, not to mention the many thousands of cases of crippling and disablement from the same germ. Another table demonstrates, what has been taught so long in this country, that bovine infection takes place during the milk consuming years—1 to 5. He repeats the statistics given by the People's League of Health, and since, officially, showing that about 40 per cent of the cattle of England and Scotland are reactors to tuberculin and estimates that about $2\frac{1}{2}$ per cent of them are infective. Udder tuberculosis is most dangerous from the human standpoint, though the pulmonary form is most dangerous to other cattle.

We have commented on the Manchester situation in which laws concerning pasteurization failed by a popular vote. In view of the statements that most of the herds of England contain from 40 to 50 per cent of reactors, that the milk is sold without supervision or pasteurization, and that there are no legislative measures which deal with the reduction of bovine tuberculosis, we cannot but stand aghast, though it is not entirely news to us.

Almost coincident with this Mitchell Lecture comes a Memorandum² and a Report³ concerning the situation in Scotland, which is admittedly in a bad case even in England. In Scotland, Glasgow appears to have the worst record of any city. The report points out that the bulking of milk as now carried on increases the danger of infection, over 30 per cent of positive results having been obtained from large bulk supplies, while the lowest incidence of infection is found in the samples obtained from small dairy farms. Savage¹ defends the bulking of milk, arguing that the dilution decreases the number of organisms found in a given sample as compared with the badly infected units which contaminate the bulk milk. It is pointed out in the Memorandum that non-pulmonary tuberculosis is preëminently a disease of childhood, that 70 per cent of the patients become infected under 15 years of age, and that in 90 per cent one or the other of three forms—bone and joint infection, disease of the abdomen, or of the cervical glands—become manifest.

Dr. Blacklock⁴ indicates that approximately 80 per cent of abdominal, 35 per cent of bone and joint, and 64 per cent of cervical gland tuberculosis in Glasgow, where he made his investigations, are of bovine origin. Non-pulmonary tuberculosis still accounts for more than 4,000 cases and 1,000 deaths annually in Scotland, of which 900 cases and 300 deaths occur in the City of Glasgow.

We are glad to note in this report a strong statement concerning pasteurization, holding, what we have demonstrated so clearly in America for a number of years, that it is the greatest single preventive of bovine infection we have, and that there is no impairment of the nutritive qualities of the milk.

In America we are fortunate with respect to control of bovine tuberculosis, largely owing to the activities of our Bureau of Animal Industry. The most recent compilation⁵ gives the death rate from respiratory tuberculosis and other forms from 1900–1932 inclusive, with some figures for 1933. In 1918, intensive testing of cattle began in many of our states, and in some, earlier (Minnesota, 1904, Wisconsin, 1911). The summary for the United States shows that the death rate per 100,000 for tuberculosis had generally decreased from 1900 to 1918, although in some areas there was a slight increase. From 1918 to the present, there has been a marked decrease in the tuberculosis rate, reaching for 1932, 56.6 for respiratory tuberculosis, and 6.4 for other forms; during that time, 115,170,388 cattle were tested and 2,693,570 reactors removed from herds. There have been other factors working, prominent among which is the increased pasteurization of milk, but when all is said and done, the eradication of tuberculosis from herds must be given due credit for the part it has played in the remarkable improvement which has taken place.

We feel a justifiable pride in the record made. We congratulate our Bureau of Animal Industry upon its excellent work, and would be glad to see the National Tuberculosis Association take an active part in this aspect of tuberculosis control.

LETTER FROM GREAT BRITAIN

APPROPRIATIONS AND ESTIMATES

In conversation with American colleagues, one of the questions most frequently put up to me has reference to the amount of "appropriation" for health purposes. Always I try very hard to avoid having this question asked, and always, although I rarely succeed, I try to avoid answering it. The reason for these evasions is that the method of appropriation, as it is understood in the United States, is not followed here, and it is so very difficult to explain just what the process is. Moreover, it is practically impossible to name a figure that would actually represent the amount expended on health works, for the reason that the group of activities coming within the purview of the health officer in Britain is not quite comparable with those under the charge of his colleague in the United States.

Further, between districts of various classes in this country there are differences, and the expenditure in one area may appear less than in another, merely because some particular type of work that is dealt with in the health department in one is the responsibility of the officer of another department in the other.

Probably nowhere are differences so marked as in the metropolis, and nowhere is the difficulty greater of giving an indication of the amount devoted to health work throughout the county as a whole, or in various of the 28 boroughs or cities into which the metropolis is divided for local government purposes. For the assistance of those concerned to discover expenditures and to make comparisons, the London County Council issues annually, by way of appendix to their annual report, a collection of

tables particularizing a number of matters. From the point of view of the health worker the most interesting of these is that headed "Expenditure of metropolitan borough councils falling on the rates" in the particular year. In this the equivalent rates in the £ are shown in regard to each borough, and in respect of a number of matters.

LONDON HEALTH FINANCE

The variations to be noted in every single branch are astonishing, and without explanation or knowledge of circumstances and conditions in the various areas, conclusions entirely erroneous would be formed. Take the treatment of tuberculosis for example. Here the expenditure practically everywhere is trivial, amounting only in three boroughs to a rate of over one penny in the £.

To account for the variations there are a number of explanations: the size of the borough and its population; the circumstances and condition of the inhabitants; the trades carried on; the amount of work done by voluntary bodies; and so forth. In connection with the lowness of the figure—the smallness of the appropriation if you like—in all cases the point to be borne in mind is that sanatorium provision and treatment are not included, this being the business of the London County Council. The position in regard to maternity and child welfare is interesting also, the amount expended in terms of rates in the £ varying from 0.2 penny to 7.7 pence. The higher expenditure, as might be expected, is incurred in the poorer areas; the lower in those of a higher class, the City of Westminster (0.2 penny), St. Marylebone (0.6), for instance.

Curiously enough also in the matter of this work, all the advantages are on the side of the high-class boroughs, since whereas in them voluntary organizations are active in assisting the municipality and in this way reducing the burden on the rates, in the poorer areas voluntary workers are few and far between, and the scheme is entirely an official one paid for out of the rates. Further, it must be remembered that in no case is the amount spent on health work for the benefit of school children included. This is an activity exclusively in the hands of the London County Council as education authority, and information as to the amount expended upon it must be sought for in the accounts of that body. All of which does not make it any easier to understand or to explain the situation in regard to health appropriations.

A CENTURY OF FACTORY HYGIENE

Though it is some months since it appeared, I find I have not yet referred to the report of the Chief Inspector of Factories and Workshops for last year. This is all the more regrettable as the year 1932 marks the hundredth anniversary of the appointment of the first government inspector of factories. It was after the passing of the Factory Act of 1833 (entitled "An act to regulate the labour of children and young persons in the mills and factories of the United Kingdom") that the inspectors, four in number, were appointed. Each inspector had power to appoint "superintendents" or "sub-inspectors." In addition to, himself, writing a most fascinating historical note by way of introduction, Mr. D. R. Wilson, the chief inspector—whose first annual report it is, by the way, since taking up the post in succession to Sir Gerald Bellhouse—includes reviews on various aspects of the work by Miss Taylor, Mr. Lauder, Dr. Bridge, and other members of the inspectorate.

In no branch of the work has the progress made during the century been greater than in health. Writing with regard to it, Dr. Bridge provides a note of extreme interest, showing the advances made in each of the main periods in which certain particular acts were operated or events, like the War, enacted. Naturally, of course, he finds it quite easy to show that very much of what has happened was anticipated at the very beginning of the era. The individual to whom credit is given for having foreseen the trend of events was a Dr. Thackrah of Leeds, who, in 1831 published a small book on the effects of the principal arts, trades and professions.

In the first period, which extended from 1833 to 1878, in which latter year new legislation came into operation, Sir John Simon, to whom preventive medicine the world over owes so much, was medical officer of the privy council, and very much to the fore. In a special report in which he appeals for improved conditions in factories, more particularly in regard to ventilation, he employs a phrase, which must have been used very frequently in the years that followed, to the effect that "the canker of industrial diseases gnaws at the very root of our national strength." Following this report, provision was made, among other matters, for modifying the hours and meal-times of children and young persons.

DICKENS AND THE LEAD WORKER

In the period of 1879–1894, the benefits of legislation giving power to require exhaust ventilation, by means of a fan, for the removal of dust likely to be injurious to health, and to obtain better sanitary conditions, were enjoyed. The employment of children in certain occupations and trade processes was forbidden, and in 1891 appeared an act in which specific attention was given to compel the introduction of methods

designed to prevent industrial diseases.

Curiously it was not till 1879 that there was reference to lead poisoning, and on this, naturally, Charles Dickens had something to say, particularly in regard to cases in which women were allowed to work in white lead factories with "naked feet" and without respirators. Dickens apparently, at the time, had a feeling that if safety for women lead workers was to be found, it was on the American side of the Atlantic it must be sought, for, says he, "American inventiveness would seem to indicate that before long white lead may be made entirely by machine; the sooner the better." The practicability of making white lead by machinery is not yet, of course, completely established; nevertheless, as Dr. Bridge shows, direct pulping of white lead in oil, eliminating the drying and grinding processes, has been in the last decade the prime factor in the reduction of lead poisoning.

In regard to lead, among other matters, Dr. Bridge pays tribute to the work and memory of Sir Arthur Whitelegge, whose appointment as chief inspector in 1896 "marks a definite stage in the development of the medical work of the department," and of Sir Thomas Legge, who was appointed first medical inspector in 1898. Medically big developments followed the appointment of these two men, many industrial diseases and conditions in industry calling for attention being noted by them and brought under control.

The period 1901-1913 was a busy one from the medical point of view, closer attention being given to lead poisoning and steps taken for dealing with anthrax. In the war period, 1914-1918, Dr. Bridge believes came realization for the first time that "conditions special to the occupation were not the only cause of industrial disease, but that other factors—fatigue, undernourishment, and other conditions met with both inside and outside the time of

employment—were as important in the production of illness as those produced by the materials handled."

FACTORY HYGIENE IN THE FUTURE

Extraordinary strides were made in relation to welfare work, and both during and immediately after the War, the practice of appointing whole- or part-time works doctors spread very rapidly. The medical staff of the department was also enlarged, and this process of enlargement was carried over into the period 1919-1931. Discussing progress and operations in these years, Dr. Bridge notes especially works done in relation to fibrosis of the lung and cancer. In regard to the latter, he mentions the discovery of the high incidence of scrotal epithelioma among cotton mule spinners, and the demonstration by Dr. Henry of the department that the introduction of mineral oil into the lubricant for self-acting mules coincided with the increased incidence. The further discovery was made that sufficient exposure to pitch, tar, mineral oil and compounds, products or residues of these, will, in a certain percentage of persons, produce skin cancer.

That the post-war period has had anxieties apart from these two conditions the review of Dr. Bridge shows. This is particularly the result of the introduction for use in industry of chemicals of a complex nature, used as solvents of cellulose and in the manufacture of synthetic compounds, for example. New industries have brought new problems, while many of the old ones still remain unsolved or in need of close observation. It is inevitable in an age of rapid progress with modern methods replacing older ones, and completely new trades and processes springing up, that this should be so, and no doubt Dr. Bridge and those with him, and those who come after, will be no less alive to the need for watchfulness, and no less capable of recognizing risks

and devising methods of coping with them than those who went before.

The annual reports of the Chief Inspector of Factories for Great Britain is a publication always of interest to workers in the field of preventive medicine; that for 1932, because it relates

to a period so extended and treats of matters so very numerous and important, is likely to provide an interest much more abiding than others of its predecessors.

CHARLES PORTER, M.D.

London

PRESIDENTIAL CORRESPONDENCE

November 23, 1933.

The Honorable
The Secretary of Agriculture
Washington, D. C.

My dear Mr. Secretary:

Members of the American Public Health Association are actively interested in the efforts of the Agricultural Adjustment Administration to improve the economic status of dairy farmers in this country through milk marketing agreements. We recognize that desirable standards of cleanliness and safety of this most important food can not be maintained where farmers continue to receive for their product less than the cost of production.

I wish, therefore, on behalf of the public health authorities in this country, to commend your efforts to place dairying upon a sounder economic basis. We have noted with interest also the provisions of Federal milk marketing agreements that milk dealers agree to all public health and sanitary requirements for their product. While the marketing agreements are designed primarily to meet an emergency situation in the economic aspects of this problem, we feel they will fall far short of their potential good to the public unless they are used also aggressively to promote the sanitary quality of milk. As you know, there are still many tuberculous cows in dairy herds. Contagious abortion assumes increasing importance from year to year as a public health menace. Milk supplies for many areas

still fall short of desirable sanitary standards.

The Federal marketing agreements provide for restriction in the production of milk. I feel it my duty to urge upon you that you consider the desirability, in any plan of production control, of eliminating milk from diseased cows and milk of low sanitary quality. In other words, with an excess of milk available it seems sound, from the economic as well as the health standpoint, to keep off the market all milk from diseased cows and milk produced under insanitary conditions.

The health authorities of this country believe that there would be no real surplus of milk if all persons availed themselves of the amount necessary to promote the optimum growth and nutrition, not only of children but of adults. We are glad, therefore, to join with you in any steps to promote the amount of milk consumption. At present the people of the United States are consuming daily less than half the amount of milk which our present knowledge convinces us should be used in the interest of health and with due regard to economy in the family diet.

If the American Public Health Association can be helpful to you in furthering the purposes which I have outlined please indicate to me how this can be done.

Yours respectfully,

HAVEN EMERSON, M.D., *President*
American Public Health Association

UNITED STATES DEPARTMENT OF
AGRICULTURE
Agricultural Adjustment Administration
Washington, D. C.

December 13, 1933.

Haven Emerson, M.D., President,
American Public Health Association,
450 Seventh Avenue,
New York City, N. Y.

Dear Dr. Emerson:

This acknowledges receipt of your letter of November 23, addressed to Secretary Wallace, and discussing the efforts of the Agricultural Adjustment Administration to improve the economic status of dairy farmers.

You refer to the fact that milk supplies for some cities will fall short of the desirable sanitary standards, and urge the elimination of milk from diseased cows and milk of low quality from dairy markets. In this connection, it will be of interest to you to

know that a committee representing the Department of Agriculture now has under consideration a plan of production control. It has as yet not been definitely decided what the final steps in this plan will be, but it is believed that the eradication of tubercular cattle, and, possibly, the elimination of cows otherwise diseased will be a part of the program.

In the several Marketing Agreements provision is also made for the consumption promotional program, and existing Agreements have been modified and new Agreements are so written that it will be possible for recognized charitable institutions to obtain milk at a low price figure.

Your offer of assistance is greatly appreciated.

Very truly yours,

E. W. GAUMNITZ,
Principal Agricultural Economist,
Dairy Section.

STANDARD METHODS OF MILK ANALYSIS, 6TH EDITION

THE changes and additions in the new edition of Standard Methods were summarized in the April, 1933, issue of the American Journal of Public Health. The new edition is in press and will be available after March 1. It will contain 88 pages, bound in hard covers with waterproof cloth. The price is \$1.00.

ASSOCIATION NEWS

63RD ANNUAL MEETING A.P.H.A.

5TH ANNUAL MEETING WESTERN BRANCH

THE American Public Health Association announces that its Sixty-third Annual Meeting will be held in Pasadena, California, September 3-6, 1934.

The Western Branch of the American Public Health Association, with a membership of more than 1,200 from eleven western states, will hold its

Fifth Annual Meeting at the same time.

Dr. J. D. Dunshee, Health Officer of Pasadena, has been appointed Chairman of the Local Committee on Arrangements. He will be assisted by Dr. John L. Pomeroy, President, and Dr. W. P. Shepard, Secretary of the Western Branch, and other prominent public health authorities on the west coast.

ROYAL SANITARY INSTITUTE MEETING AND HEALTH CONGRESS

THE Executive Board wishes to call attention to the meeting of The Royal Sanitary Institute which is to be held in Norwich, England, from May 15 to May 20, 1934, and to the Health Congress to be held under the auspices of the Royal Sanitary Institute at

Bristol, England, July 9-14, 1934; and asks that any members who plan to attend, or who may be in England at that time and can attend, will notify the Executive Office so that they may be appointed official representatives of the Association.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

Norman C. Bullock, M.D., City Hall, Rockford, Ill., Commissioner of Health
Bertrand F. Drake, M.D., 425 Beechmont Drive, New Rochelle, N. Y., City Health Officer
George B. Edwards, M.D., Darlington, S. C., County Health Officer
Dr. Thomas J. McCamant, 209 S. Campbell, El Paso, Tex., Director, City-County Health Unit
Howard Morrow, M.D., 384 Post St., San Francisco, Calif., President, Calif. State Board of Health
Samuel B. Ross, M.D., Hotel Roosevelt, New York, N. Y., Medical Inspector, City Dept. of Health

Lec A. Stone, M.D., Box 56, Madera, Calif., County Health Officer
W. Bradford Walker, M.D., Cornwall, Conn., Health Officer

Laboratory Section

Earle K. Borman, M.S., State Dept. of Health, Hartford, Conn., Assistant Director of Laboratories
Frederick D. Carr, 73 Main St., Batavia, N. Y., Director, Genesee County Laboratory
Caryl C. Carson, M.S., 166 Freeman St., Hartford, Conn., Chief Chemist, Bureau of Laboratories, State Dept. of Health
Stephen H. Curtis, M.D., 80 First St., Troy, N. Y., Director, Leonard Hospital Laboratory

Robert B. Dienst, Ph.D., 5649 Woodlawn Ave., Chicago, Ill., engaged in Amebic Dysentery Survey, Chicago Board of Health

Michael Grimes, Ph.D., M.S., Dept. of Dairy Bacteriology, University College, Cork, Irish Free State, Dairy Bacteriologist (Associate)

Ernest B. Hanan, M.D., A.B., 462 Grider St., Buffalo, N. Y., Director of Laboratories, Buffalo City Hospital

Cyril K. Johns, M.Sc., Central Experimental Farm, Ottawa, Ont., Canada, Dairy Bacteriologist, Dominion Dept. of Agriculture

John E. Kieffer, 206 Huntington Ave., Buffalo, N. Y., Graduate Student (Associate)

I. A. Merchant, Ph.D., D.V.M., Yale School of Medicine, New Haven, Conn. (Temporarily on leave), Professor of Veterinary Hygiene, Iowa State College, Ames, Ia.

Julius Pincus, M.D., 250 W. 75 St., New York, N. Y., Director of Clinical Pathological Laboratory

Celia Rubin, 62 W. 91 St., New York, N. Y., Student (Associate)

Joseph R. Sanborn, Ph.D., 133 Ridge St., Glens Falls, N. Y., Bacteriologist, Research Division, International Paper Company

Anna M. Stuart, M.D., 656 Park Place, Elmira, N. Y., City and Chemung County Laboratory Worker

Public Health Engineering Section

William McL. Bingley, B.E., 3623 Spalding Ave., Baltimore, Md., Assistant Sanitary Engineer, Chlorine Institute

Robert W. Kehr, C.E., U. S. Public Health Service, Cincinnati, O., Assistant Sanitary Engineer

C. H. Young, S.E., Trust Bldg., Meadville, Pa., District Engineer, State Dept. of Health

Food and Nutrition Section

Joy C. Wickham, V.S., 1905 Cypress St., Cleveland, O., Milk Inspector

Child Hygiene Section

William J. Ryan, M.D., Pomona, N. Y., Superintendent and Medical Director, Rockland County Tuberculosis Sanatorium.

Public Health Education Section

Adelheid Arfsten, A.B., 600 Stockton St., San Francisco, Calif., Pacific Coast Welfare Supervisor, Metropolitan Life Ins. Co.

Muriel F. Bliss, C.P.H., 697 Park St., Attleboro, Mass., Health Education Research Worker, Mass. Inst. of Tech.

Lily A. Craighan, R.N., P.H.N., Dept. of Public Health, San Francisco, Calif., Supervisor of Health Education

Public Health Nursing Section

Theresa M. Gartner, R.N., Box 252, Tucumcari, N. Mex., School Nurse

Mattie M. Washburn, 325 State St., Albany, N. Y., Assistant Director, Div. of Public Health Nursing, State Dept. of Health

PUBLIC HEALTH ADMINISTRATION

Christmas Seals Finance the Campaign Against Tuberculosis

HEALTH RECOVERY CAMPAIGN

EVERY health officer should participate during 1934 in what has come to be known as the Early Diagnosis Campaign, sponsored by tuberculosis associations. The slogan selected, the art design, the printed matter, and newspaper cartoons are all designed to create popular understanding and support of public health activities. Tuberculosis workers are being urged by their leaders to broaden the scope of their health education efforts and to invite all health workers, official and nonofficial, to join with them for the sole purpose of promoting public health.

The slogan: "Tuberculosis Robs You—Public Health Protects You" has been selected for general use by tuberculosis associations throughout the country, but it is not essential that this slogan be used exclusively—it may be adapted to express the immediate health problem. A manual of suggestions has

been prepared for the use of organizers of committees, which emphasizes the importance of making the movement one of the public health group as a whole, subordinating tuberculosis control to whatever relative place in the program it may take by common consent of the members of the committee.

The objects of the campaign have been thus set forth in the preliminary material placed at the disposal of local tuberculosis associations and committees, which is also available through them to other organizations:

1. To increase the general public's appreciation of the benefits it derives from good public health services, with emphasis on the official health department's work, and its needs.

2. To cause the public to demand adequate public health service.

3. To coördinate with the health department the efforts of all voluntary health agencies, as well as civic organi-

zations, clubs, and outstanding individuals to the above ends.

There are to be two posters, one 24-sheet, and the other car card size, the latter supplied printed on cardboard and on paper. The design shows a robber about to escape with his spoils when he is interrupted by a heroic figure with a flaming sword. The caption is "Tuberculosis *Robs* You—Public Health *Protects* You."

Three pieces of printed matter will be provided for use in the campaign.

"Tuberculosis *Robs* You—Public Health *Protects* You," a 4-page circular for wide distribution among the public as a whole at meetings, through interested groups, as enclosures in letters. It tells, briefly, the need for adequate public health protection in terms of what this means to the individual, especially with relation to tuberculosis.

"Mr. Taxpayer Goes Shopping" is intended to help obtain the cooperation of organizations, and should be used with persons in a position to influence

the action of groups to participate in the campaign; leaders in community and civic life. It dramatizes the idea of the average man shopping for his government activities; almost forgetting public health, until he is shown how little it costs in comparison with how much it does for him. The reader is invited, at the end of the leaflet, to join the campaign.

"You Don't Say!" A series of statistical statements supporting the slogan of the campaign, for the information of community leaders, office holders, educators.

A set of 14 cartoons, a single column in width, has been prepared for use in newspapers, and other periodicals, 4 of which are shown in this article. They illustrate such statements as the following, which appear as part of the cuts which will be supplied ready-to-print:

We spend thru taxes about 1 cent per week for health protection (the cost of only 2 cigarettes)

Public Health FACTS

Police protection taxes each person about \$4.52 per year
Health protection about 50¢

Public Health FACTS

We spend thru taxes about 1 cent per week for health protection (the cost of only 2 cigarettes)

Public Health FACTS

From 1911 to 1931
average length of
life was increased
7 years (U.S.A.)

\$2 per person a year will operate
a fully efficient health department.
Our cities now spend only 75¢ per
person

Public Schools are a bargain at \$16.17
per person
Public Health struggles along on 50¢
per capita

VITAL STATISTICS

Negroes Hard Hit by Tuberculosis—Nearly one-fourth of all deaths from tuberculosis in Illinois are among negroes and other colored races, although they make up less than one-twentieth of the population. Mortality from tuberculosis among negroes in Illinois is 6 times greater than among whites. The death rate from this disease among Illinois negroes is more than twice the death rate from tuberculosis among negroes in Arkansas, Florida, Georgia, Louisiana, Mississippi, or South Carolina, and much greater than in any of the other southern states. About 1 in each 6 deaths from all causes among Illinois negroes results from tuberculosis, whereas among white in this state that disease accounts for only 1 in each 25 deaths.

Furthermore, the progress toward eradicating tuberculosis in Illinois has been much less among negroes than among whites. During the last decade the death rate from tuberculosis among negroes in Illinois has declined only 19 per cent while that among whites has been reduced 45 per cent. Expressed in another way, the rate of decline has been more than twice as great among whites as among negroes in this state.

Only heart impairment causes more deaths than tuberculosis among negroes. Among whites, on the other hand, heart disease, cancer, nephritis, apoplexy, and pneumonia are all much more frequent causes of death than is tuberculosis. Whereas tuberculosis caused only 45 deaths per 100,000 population among whites in Illinois last year, it was responsible for no less than 260 per 100,000 among negroes.

These are facts that cannot be overlooked in the future program against tuberculosis. The more rigorous climate

is perhaps a factor in causing a higher rate from tuberculosis among negroes in Illinois than in the South. Congestion of the negro population (about 240,000) in Chicago is probably another important factor.—*Illinois Health Messenger*, 5:94-95 (Dec. 15), 1933.

Mortality Data for Hong Kong in 1932—The Medical and Sanitary Report of Hong Kong for 1932 contains some interesting data concerning the mortality statistics of the Colony.

In 1932, the civilian population of the Colony had a crude death rate of 24.74 (per 1,000 population) from all causes—a slight increase over the corresponding rate (24.08) for the previous year. The Chinese population alone, which includes 98 per cent of the total population, had a general death rate of 25.02 in 1932 and one of 24.39 in 1931; the non-Chinese experienced a 1932 mortality of 14.16 (per 1,000 population)—a substantial increase over the rate of 11.83 for the previous year. Examination of the infant mortality data shows that the non-Chinese population lost 97.93 infants per 1,000 registered births in 1932, a rate 58 per cent higher than that (61.85) in 1931. It is difficult to calculate an infant death rate among the Chinese population since only a part of the births are reported—yet it is generally admitted to be abnormally high.

Analysis of the mortality by causes of death among the civilian population reveals broncho-pneumonia at the head of the list, rates of 323 and 361 (per 100,000 population) having been recorded for that disease in 1932 and 1931 respectively. Pulmonary tuberculosis was second with death rates of 252 and 260 in the same 2 years. Other leading

causes of death in 1932 were bronchitis with 112 deaths per 100,000 population; diarrhea (infantile)—160; diarrhea (over 1 year)—140; nephritis—89; and heart disease—66.—Tables from *Hong Kong Medical and Sanitary Report*, p. 26–30, 1932.

The Threat of Violent Death to the Male—Why is the mortality of males nearly everywhere higher than that of females? In the early months of life, when the relation of the infant to the external world is essentially the same for both sexes, the higher mortality of the male child can be due only to constitutional causes. That the male child is indeed somewhat more delicate than the female is indicated, among other things, by the fact that among stillbirths males exceed females by over 30 per cent. And even the principal communicable diseases of childhood, namely, measles, scarlet fever, and diphtheria, show a higher death rate among boys than among girls. But when childhood years are past, indications are that constitutional factors play a subordinate part in determining the excess mortality of the male over that of the female. Analysis of the various causes of death, as they affect the two sexes respectively, bears out this view. It is to the external factors that one must look for an explanation. Even in the very earliest years the boy is more venturesome than the girl, and throughout later boyhood, adolescence and his entire adult life, the male is subjected to external dangers not encountered in anything like the same degree by the female.

Analysis of the mortality statistics for the years 1929–1931 among white persons in the U. S. Registration States, as of 1920, clearly reveals this handicap of the male. During the preschool period, or, to be more exact, among children of ages 1 to 4, the death rate from accidents was 70.0 per 100,000 among

boys, as against only 54.3 among girls. At these ages, however, deaths from violent causes form a large part of the total for either sex, taking almost as heavy a toll as measles, scarlet fever, and diphtheria combined, both among boys and among girls.

During the next 10 years of childhood, accidents and other forms of external violence produce a far greater number of deaths among boys than any other single cause. Over one-quarter of the deaths of boys at this age were due to accidents alone. In fact, more schoolboys die as a result of accidents than from all of the usual communicable diseases combined, including influenza-pneumonia and tuberculosis. The accident death rate of boys of this age is almost $2\frac{1}{2}$ times that of girls, 52.7 per 100,000 as against 21.8.

The main working period of life, ranging from 15 to 49 years of age, represents the term of man's greatest exposure to the hazards of industry and of civil life. It is, therefore, not surprising to find that there are more deaths due to external violence among men than from any other cause; practically twice as many male deaths result from violence during these years as are caused by tuberculosis (all forms). The male death rate from violence at ages 15 to 49 exceeds that of females by more than 4 to 1 (142.1 against 33.2). This age period comprises the most productive years of a man's existence; the years during which his value to society is greatest. It is precisely at this time of life that the sudden loss of the head of the family is most disastrous. Great stress has been laid on the needlessly high maternal mortality rates in our country; but the question may well be raised whether the regrettably high maternal death rate is not far exceeded in serious consequences for society and the family by the high and largely avoidable death rate from violence of various sorts among male wage earners.

The combined mortality rate of men from accidents, homicides and suicides during this age period is just $3\frac{1}{2}$ times that of women from causes related to pregnancy and childbirth. If the deaths both from violent causes and also from puerperal causes could be entirely eliminated during this period of life, the mortality of both sexes would not be far different, namely, 376.1 per 100,000 for men as compared with 342.0 for women.

After age 50, the rising tide of deaths from the chronic or degenerative diseases tends to obscure the importance of the violent causes. Nevertheless, the latter remain among the chief causes of mortality among men to the very end of the life span. In the 5-year age period 50-54, the male death rate from external violence is exceeded only by that from organic heart disease. Violence, at this age, is responsible for more than 4 times as many deaths among men as among women (220.6 per 100,000 as against 54.2).

During the next 10 years of life, 55-64, violent deaths among men are outnumbered only by those ascribed to heart disease and cancer. After 65, however, violence as a cause of death is outranked by several diseases, notably heart disease, cancer, cerebral hemorrhage, nephritis and pneumonia.

Although external violence ceases to be the chief cause of death among men after age 50, it nevertheless continues to exact an increasing toll of deaths as old age approaches. Mortality rates from violence in the years 1929 to 1931 combined, among white persons, at the successive age periods were approximately as follows:

RATES PER 100,000

Age Period	Males	Females
45-49	198	44
50-54	221	54
55-64	262	78
65-74	335	167
75 and over	615	692

It is interesting to observe that, as old age advances and the greater activity of the male gradually diminishes to the level of that of the female, the accident death rates for the two sexes more closely approach each other. In fact, it is observed that in extreme old age, accidents were even more frequently the cause of death among women than among men. At this stage of life, vigor ceases to be a factor in violent deaths; instead, the underlying causes are those associated with senescence.

The facts thus brought out by a study of the deaths from violent causes among males and females by individual age groups are also reflected in the average death rates for all ages, as follows:

During the 3-year period, 1929 to 1931, the average death rate from all causes among white males in the Death Registration States of 1920 was 1,094.1 per 100,000, as against 933.7 among white females. In other words, among every 100,000 white males there were 160 more deaths than occurred among an equal number of white females. At the same time the death rate per 100,000 from external causes among males was 148.6, while that of females was only 54.6. Thus, of the 160 extra deaths from all causes among white males, 94 or 59 per cent were attributable to external violence. The deaths from these causes were almost 3 times as many among men as among women.

Fortunately, this excess is capable of reduction by means actually within reach. The various factors in industry, in sport, and in personal habits, which create the special risk for the male, are subject to modification, if sufficient attention is drawn to them. Much has already been done in this direction by such organized efforts as the Safety First movement; but much more still remains to be done. When the full effect of such measures is rendered available, much wastage of human wealth will be prevented, and great gains will be

secured for the individual, for the family, and for the nation.—*Stat. Bull., Met. Life Ins. Co.* 14:3–5 (Nov.), 1933.

Maternal and Infant Care in North Carolina—Since great stress has been laid on the subject in recent months, every reading citizen of the State of North Carolina should have become cognizant of the fact that both the maternal and infant mortality in the state are higher than the national average. The problems of maternal and infant mortality are so closely inter-related that one cannot be discussed without study of the other.

In North Carolina, puerperal causes accounted for 555 deaths and a death rate of 7.2 (per 1,000 live births) among mothers in 1932. In the same period, 5,459 babies died before the end of their first year of life—equal to an infant mortality of 70 (per 1,000 live births). Further analysis shows that 2,424 of the infants died before they were 13 days old; even more deplorable was the fact that 1,209 or more than 1 out of 5 died before they were 1 day old.

Opinions may differ, but all thinking citizens realize that the question is a rather involved one and that the blame cannot be placed on any one doorstep. A number of causes contribute to the high infant and maternal mortality. It is natural to assume that the first place for an investigation is the attendance and care which each expectant mother has received from the inception of her pregnancy to and including the safe delivery of a normal baby.

An examination of the statistics in North Carolina in 1932 shows that midwives delivered about 34 per cent of the women in childbirth for that year. It will be noted that 8,121 white women

were attended exclusively by midwives. Of the 34 per cent attended by midwives, none had the benefit of any form of medical prenatal service except in the instances where upon the direct request of the midwives literature was supplied to them by the State Board of Health. No exact figures are available to prove that, of the remaining 66 per cent attended by physicians, about one-half had the services of the physicians only from the onset of labor; yet it is a safe estimate. This means that about two-thirds of the women in North Carolina go through their pregnancies without any form of direct personal medical prenatal service whatever. For several years, the State Board of Health has been doing its utmost to improve the services of midwives. Toward this end, 6 competent nurses were sent into 56 counties of the state in an effort to impart some instruction to each midwife carrying on her vocation. These nurses examined 1,108 midwives. The nurses found that following their summer's instruction, 224 had the fully equipped bag which the department recommends for midwives to carry; 403 had partially equipped bags; and 454 had no equipment whatever—not even a bar of soap or a pair of scissors.

In almost every one of the aforementioned counties, the county board of health readily agreed to adopt resolutions conferring authority on the State Board of Health and the official county physician to regulate the practice of midwifery for a period of 1 year.

It is the aim of the State Department of Health some day to achieve the now impossible ideal, which is competent medical service and competent prenatal service for every expectant mother in the state.—*North Carolina Health Bulletin*, 48:3–5 (Dec.), 1933.

PUBLIC HEALTH ENGINEERING

THE PRACTICAL APPLICATION OF MILK CONTROL*

J. R. JENNINGS

Chief, Division of Milk Control, City Health Department, Louisville, Ky.

MILK control is extremely young in a modern sense, having as its start the certified milk movement in 1892. It was not until 1907-1910 that states and municipalities considered it of much importance. Since that time, there have been developed three principal types or systems of milk control, namely; the "Scoring" system, the "Force" or "Thou Shalt" system, and the "Grading" system. All are intermingled with variations. I shall attempt here to give the merits of each in the light of my experience.

The scoring system came along about 1903 and was useful in educating the dairy industry and the consumer to the fact that milk needed protection from a sanitary standpoint. However, it was soon discovered that it was lacking in certain fundamentals, particularly in that it did not get results among a large part of the industry, and especially the inferior part. For example, A few producers and distributors, being of a higher type, regularly received a higher score than the remainder. The mediocre and the careless or ignorant ones then became negligent, discouraged, or disgruntled. The inspector was accused of favoring those with a high score and "picking on" those with a low score. When the inspector said to the dairyman: "Your barn floor is filthy today.

You must get that in better condition," the dairyman replied: "Yes, I noticed you scored me down on that the last time, but I have been busy and I get just as much for my milk." This system does not get desirable results because of numerous similar situations both in pasteurization plants and on dairy farms. There is another important weakness in this system. Assume that the pasteurization plant does a poor job of sterilization or the raw distributor has a contaminated water supply, but all other things are complied with. Both are given a score of 97 per cent or 98 per cent—probably the highest scores in the city. Yet both are potentially dangerous. The public is consuming this milk with a false sense of security. These defects then led health authorities to the adoption of the force system.

This system, briefly stated, reads something as follows: "It shall be unlawful for any person, firm, or corporation to sell milk in the City of, unless all of the following items of sanitation are complied with." The items are then listed and are much the same as those appearing on the score card used with the scoring system. Theoretically, this type of control is ideal, but from a practical point, and in all but exceptional cases, it is probably the poorest.

As an illustration, the law or ordinance will require, along with many other items, that the milk plant or

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 19, 1933.

milk house, as the case may be, shall be fly tight and contain no flies. The inspector makes a call and finds the milk bottles covered with flies and proceeds to give the plant foreman or dairyman a warning or perhaps a severe reprimand. On the following visit, the inspector may find things as bad or worse and serves notice that the establishment is "closed up." If the dairyman has influence politically, or if the bank he owes money to has influence, and it frequently has, he will likely be reinstated over the inspector's head.

He may take the matter to court, in which case the inspector may fail to prove that the milk in question has killed anyone or even made anyone sick. The judge or jury in most such cases, will then render a verdict "not guilty," due to the fact that the penalty is too great for the offense.

After having several such experiences, the inspector mumbles to himself, "What's the use?" He knows, and the dairy industry knows, that he is beaten, and he continues with nothing but the persuasion he is able to muster. He finds to his dismay, in many cases, that not only the courts, but the public, and even the law making body that passed the ordinance, will not support him in its enforcement.

If it were not for these things, the force system would succeed more frequently. He also learns that it is not fair and just that a milk distributor be closed up on many of the items specified by the law or ordinance. His own sense of fairness rebels against it. For these reasons the grading system of milk control has come into wide usage during the past 10 years.

The difficulties mentioned happen with much less frequency when the grading system is used, provided several grades are established. If only one grade is established, the program will be worse than the force system, because there is no penalty left except to close

up the distributor. Since in most cases that is impossible, for the reasons given, the "Grade A" cap then appears on low grade milk. The items required in the grading program are much the same as those in the other two systems, but the lower grades are provided for enforcement purposes only. The inspector determines the grade and the housewife does the enforcement.

The distributor soon learns that he must keep a "Grade A" rating or he will lose his business. He would also much prefer a stiff fine in court than to have his competitors know that his grade has been lowered. We may all agree that only the best grade of milk should be sold. In my experience, the simplest, the most speedy, the surest way, and with by far the most harmony between health departments and the industry, to get a good milk supply, is by the use of the grading system. The public, the courts and law making bodies support a program of this type when it is known that the penalty is not the severe treatment of closing a legitimate business, but simply requires that the distributor label his milk according to the degree of safety surrounding its care. The inspector tells the distributor that he has no desire to stop him from selling milk nor to take him to court upon violation of the milk ordinance, but that he must label his milk "Grade C" or "Grade D." When the housewife sees the lower grade rating upon the milk bottle cap or the item in the newspapers, she advises the milkman that she is changing to a "Grade A" dairy.

When the milk grading program was begun in Louisville, conditions were much the same as those existing in most of our metropolitan areas where milk control is inadequate and ineffective. Barns were dark, dirty, and dingy; milk houses were either nonexistent or largely unsatisfactory; equipment was battered and broken and of improper type; and

sanitary methods were little better. Due to a spirit of coöperation engendered into the industry by a competent and tactful application of the grading system, results were accomplished in a period of 4 months that would have been impossible with the scoring or force system. Milking barns became properly constructed, well lighted, and clean. Adequate 2-room milk houses were constructed to accommodate properly the cleaning and storage of equipment, and the cooling and care of the milk. Laboratory facilities were enlarged, and frequent examinations of all milk supplies were made. Pasteurization plants were also put in order including the most modern equipment and methods and were required to handle nothing but graded milk.

This type of control works as well in a town of 1,000 people as it does in the metropolitan areas. It works in a municipality where the temperature is 115° F. in the summer and in another that is snowed under all winter. The only reason it will not work in any part of America is politics.

But no system will bring satisfactory results if enforcement is in the hands of incompetent or uninformed personnel. One of the greatest curses heaped upon milk control agencies is the political patronage thrust upon them. In addition to having a good background, education, and experience, no inspector should be employed who does not have good approach, tact, and ability to work with the dairy industry without

causing unnecessary trouble. Wisely, Louisville milk inspectors have been employed impartially only after thorough written and oral examination.

The objective of both the health department and the industry should be the same—more and better milk. Every health department should let the industry know that when the milk is clean and safe, it will help in educating the public to the necessity for increased milk consumption. To this end our Health Department sponsored a big parade through the business section of the city; 3-minute-picture-trailers were run for a week in all picture shows; window displays were placed throughout the city; a milk pageant was attended by thousands of our citizens; bottle collars bearing a statement by the director of health about milk went out on all milk bottles; a moving picture, made locally, showing the care of milk from the farm to the doorstep was shown to numerous civic groups and schools; many radio talks were made by leading health workers and numberless other things done to acquaint the consumer with our milk supply.

Contrary to the opinion of some, this type of milk control is not more expensive than others. When results are considered, it is less expensive. Our program has been handled at a cost of less than 8 cents per capita annually in Louisville. Direct taxation bears no part of the expense of this service. It is borne by and with the approval of the milk distributors.

FOOD AND NUTRITION

Added Vitamins—Where the nature of a food does not admit of artificial color being used as an indication of high quality, the food is often advertised as being of specially high vitamin content. Instances abound where the name of the product or its description in advertisement implies the possession of high nutritive properties which have little or no foundation in fact.

These things are not quite in the same category as the ordinary commercial advertisement, which habitually exaggerates the value of its wares. They must be looked upon as likely to disturb the normal intake of special ingredients, and so bring dietetics or education propaganda into disrepute, making more difficult the dissemination of sound knowledge on nutrition.

There is a tendency at the present time for manufacturers to avail themselves of the publicity value of recent vitamin research by adding vitamins empirically to a variety of foods without due consideration of the results which may accrue from such haphazard practices. If a halt is not called to this indiscriminate dosing of foods with vitamins there is a possibility of a disturbance in the balance of nutrition which may have wide-reaching effects, and which it is not unreasonable to contemplate with some uneasiness.

Another aspect of the matter is the risk of hypervitaminosis. Although, if the diet is normal and contains a sufficiency of milk, the danger from hypervitaminosis in children would not appear to be great, there is evidence which suggests that, under certain conditions (especially when the diet is lacking in milk or when the calcium intake is high and the phosphorus intake low), the risk of hypervitaminosis has

to be seriously considered. It is not impossible that such conditions might occur in children receiving a faulty diet poor in milk and consuming appreciable quantities of bread dosed with irradiated ergosterol.

There are many other foods which are frequently or consistently debased in quality as a result of competition between manufacturers. It is difficult to say in most cases whether this debasement in "quality" implies actual reduction in nutritive value, or whether the purchaser is prejudiced merely on esthetic grounds, or, because he is not getting precisely what he asks for, or expects to get.—Taken from The Chief Medical Officer's Report, *The Pharmaceutical Journal of Great Britain*, Sept. 23, 1933.

Pellagra—New Theory Concerning Etiology and Treatment—Although pellagra is commonly described as a deficiency disease in which vitamin G plays an important rôle, the exact etiology is unknown. At least one investigator urges caution in ascribing it to vitamin deficiency alone, and this is supported by the observations of several physicians. One of the clinical features of the disease is the pathological changes of a degenerative nature in the intestines which strongly suggests that the absence of a hormone or some unknown factor or factors are responsible.

The author believes that pellagra is probably not an infection, that there is positive evidence of dietary or food insufficiency and a possibility that the colon, ileum and jejunum generate a hormone or a factor essential to normal tissue metabolism.

In view of the degenerative changes

in the intestines, particularly the structural alterations of the colon and ileum, a hypofunctional intestine is suggested. This degenerative tendency is the result of an absence of an unknown factor which results in the absorption and utilization of the mucous membrane of the ileum, jejunum and colon in an effort to secure the metabolic factor. This metabolic principle is designated as X_1 and X_2 pellagra factors.

There exists in the animal gut in the mucosa, soluble, digestible protein-like material and an unrecognized soluble factor designated as " X_2 factor." Dehydrated hog ileum and jejunum were prepared by a manufacturing drug firm by removing the mucosa, by scraping and dehydrating at low temperature with subsequent extraction to remove the fat. The resultant whitish powder is easily mixed with water, milk, orange or tomato juice. It can also be extracted by salt solution (1:5), yielding a fairly thick yellow-red solution. This solution precipitates with alcohol and phenol, resulting in a fine white powder. This powder was used in the treatment of several cases of pellagra and marked improvement resulted in 9 out of 10 patients, particularly reduction of the buccal inflammation and lessening of pain and soreness. There was a cessation of diarrhea where present.

On the basis of these tests, this material appears of definite value and it can be cheaply prepared and easily administered. The author proposed to perfect an extract for intravenous use and to establish the identity of the X_2 factor.—Abstracted from a paper by Jack Clayton Norris which was delivered before the Food and Nutrition Section of the A.P.H.A. at Indianapolis, 1933.

Vitamin C in Citrus Juices—In view of the recent work practically confirming the identity of vitamin C with ascorbic acid as well as the relationship

between the amount of ascorbic acid determined by titration with dichlorophenolindophenol and the antiscorbutic value of the material, a number of experiments were undertaken to determine the degree of natural variation in ascorbic acid content of citrus juices and its resistance to storage conditions. The authors conclude as follows:

1. The method of titration with dichlorophenolindophenol has been applied to the examination of a number of samples of lemon and orange juices, both freshly prepared and preserved in various conditions.

2. It has been found:

- (a) The reducing power of fresh lemon juice is subject to considerable variation, the lowest samples examined having only 60 per cent of the reducing power of the highest.

- (b) The reducing power of orange juice is more constant and rather higher than that of lemon juice.

- (c) The reducing power of both juices does not diminish much in storage in the absence of preservatives, but the use of any preservative which is efficient in preventing fermentation is followed by the gradual diminution of the reducing power which totally disappears in, at most, a few weeks.

- (d) The same result is brought about by strong acidification, pasteurization, or boiling.

3. It is concluded that in untreated juice the reducing factor is protected from atmospheric oxidation by the action of an enzyme, and that when this action is inhibited by any of the usual means the reducing power is rapidly lost.—

Alexander Hutcheon Bennett and David John Tarbert, *Biochem. J.* 27, 4:1294, 1933.

A Deficiency Disorder Induced in Suckling Young Rats Bred on a Purified Synthetic Diet with "Glaxo Casein" (Caseinogen) as Sole Source of Protein—In a previous abstract (*A.J.P.H.* 23:163, Feb., 1933), attention was called to the dietary factor designated "physin" obtained from mammalian liver and not identified with any of the known vitamins. In connection with this work the abnormal behavior of several litters led to

the present experiments to determine the reasons for variation.

Young rats separated at weaning from the stock diet from 4 to 5 weeks were placed on the synthetic basal ration which was fed *ad lib.* After 16 to 20 weeks the animals were mated and during gestation and lactation only synthetic diets were used.

The original diet was modified by substituting "Glaxo casein" (caseinogen) for "light white casein B.D.H." (sodium caseinate). All diets included cod liver oil. On the sodium caseinate diet, while failure of lactation is common, in no case when the mother started to feed the offspring was there failure to rear them successfully, and the young showed good growth rate.

The rats on the caseinogen diet showed the same failure of lactation in many cases. However, the mothers which did start to feed the young were successful in only a small percentage in rearing. The offspring were much undersized in weight compared to the caseinate diet. Definite pathological symptoms were evident on the 24th day.

Added supplements either to the basal

diet or directly to the young offspring were of curative value. Substituting sodium caseinate for caseinogen resulted in complete recovery while the controls died. Extracting the light white casein (caseinogen) with acetone failed to remove all of the factor, but the extracted substance was markedly less effective. Administering the acetone extract resulted in two cases of recovery compared to death of the control animals. Good results were also obtained by feeding a physin extract, resulting in rapid recovery, gain in weight and disappearance of pathological symptoms compared to death in controls not receiving this substance.

No variations in the results of these experiments were noted, either when manganese was added to the diet or when sufficiency of vitamin E was assured. The author discusses the possibility of the identity of physin with the so-called Coward factor. Further studies are to be pursued to eliminate definitely the possibility of protein deficiency or of some toxic substance in the protein.—L. W. Mapson, *Biochem. J.* 27, 4:1061, 1933.

CHILD HYGIENE

INFANT MORTALITY DUE TO RESPIRATORY DISEASES

HAVING noted that infantile mortality due to diseases of the respiratory system, and especially to influenzal broncho-pneumonia, is high, while that caused by digestive troubles is gradually being lowered, the rapporteur considers in particular the banal and influenzal infections of the upper air passages among babies, since efficacious prophylaxis of these diseases is of the utmost importance if we are to reduce mortality from broncho-pneumonia. After recalling briefly the principal clinical signs of catarrhal affections of the upper air passages and of the pharynx—which it is usual to call influenzal affections—and particularly their contagious and epidemic character, he proposes the consideration from the point of view of prophylaxis, of the ensemble of these infections whose etiology, in spite of much research, still remains obscure. He reviews shortly bacteriological research into the common influenzal forms and into pandemic influenza, noting specially the pneumococcus, the streptococci, Pfeiffer's bacillus, the filterable viruses, the *B. pneumosintes*, and the filterable forms of Pfeiffer's bacillus.

Professor Frontali admits the collaboration of diverse microbic species in the different influenzal manifestations. But it is probable that there is some other agent, not yet accurately identified, which plays a fundamental part in lowering the resistance of the respiratory system to the other germs which form its customary flora. It is not possible, however, to exclude the possibility of certain affections of the upper air passages being due primarily to

germs existing in the customary flora. From epidemiological data it may be deduced that this agent is transmitted from the sick to the healthy, from mucosa to mucosa, by atomization of the saliva. The agent makes little resistance to exterior destructive influences. However, instrumental transmission may be admitted to occur from objects freshly soiled. There is no transmission by an unaffected third person; no "carrier" has been discovered. As soon as convalescence sets in, the patient is not contagious.

In connection with the etiological problem Professor Frontali touches on the problem of immunization which has been studied with a view to confirming the data of etiological research (agglutination, fixation of complement, using as antigen the bacillus of Pfeiffer). These latter reactions appear positive during illness and convalescence in adults and children of more than 6 years, more frequently than in children of from 1 to 5 years. Systematic research with regard to other germs, at regular intervals after convalescence, is to be encouraged.

In influenzal affections, one observes, generally, a cyclic evolution which makes one think of a possible important reaction making for immunization. But from the clinical point of view it is impossible to admit the existence, in influenzal affections among little children, either of permanent immunity or of immunity for any length of time. Influenza may repeat in a baby treated in hospital at intervals of from 2 to 5 weeks. From the clinical standpoint we must look upon immunity-resistance following an attack of influenza as ex-

tremely problematic, and in any case as being of short duration.

The rapporteur then notes the *tendency* of the mucosa of the upper air passages when attacked by a virus to give rise to an infection. The antibacterial and vibratile defenses of the pituitary mucosa may be modified, directly or indirectly, by many influences, such as chill, over heating, the super-dry air of centrally heated rooms in winter, the inhalation of irritating dust or vapor, and so offer diminished resistance to the customary flora or to the specific agent of influenza. The same influences may cause a congestion favorable to bacterial invasion of the mucosa or of the sub-mucosa—cavernous tissue rich in blood.

Climatic conditions, by acting on the local and general resistance of the organism, and probably also on the biological conditions (virulence) of the microbes in question, play a highly important part in the frequency of influenzal attacks during the different months of the year. (Here follow certain statistical and climatological data.)

Susceptibility to influenzal affections varies with age. The generally admitted low frequency of these affections in the newly-born, and during the first 2 or 3 years of life, may be explained by the anatomic conditions of the mucosa and by the *eutrophia* assured by breast-feeding usual at this time. The importance of the passage of antibodies from the mother to the fetus through the placenta, or to the baby by the mother's milk must not be exaggerated, when we reflect on the relatively short duration (weeks or months only) of the immunity that the greater number of influenzal affections assure even to adults. With the exception of this early period, influenzal affections occur more often, as is shown by statistics, in the first and second year than in the following years of childhood.

The alimentary factor has considerable influence on the predisposition to influenzal affections in early childhood, on the frequency of such affections, and especially on their gravity and prognosis. These infections, statistics show, are less frequent, and in particular less serious, in the well-nourished breast-fed baby than in the normal artificially fed baby, while they are a grave danger for the bottle-fed baby that suffers from nutrition troubles.

Professor Frontali does not hesitate to affirm that a well considered system of artificial feeding rich in fats (particularly, in his oleofarinaceous food) assures better resistance than that obtained by preparations poor in fats and rich in carbohydrates.

Shortage of the liposoluble A (anti-xerophthalmic) leads to anatomical changes in the mucosa of the conjunctiva and the upper air passages with a patent reduction of resistance to various infections. The exhibition of factor B (anti-beriberic) exercises a well known influence on the whole metabolism of growing organisms, but particularly, according to Professor Frontali's personal experience, on the metabolism of fats by increasing their tolerability.

The latent and effaced forms of the lack of factor C (antiscorbutic) are accompanied by a distinctive dysergy to infections of the upper air passages. The tests (capillary fragility, capillaroscopic appearances) proposed by Professor Frontali show that the latent and effaced forms of infantile scurvy are not infrequent among artificially fed children.

Rickets, considered by many to be a D avitaminosis, is accompanied by an admitted predisposition to infections of the air passages, linked in part to deformations of the thorax and to changes in the respiratory mechanism. These infections in turn aggravate the conditions of avitaminosis in general, and in particular those that make for rickets.

In the pathology of early childhood avitaminoses and infections of the air passages form a vicious circle, accounting for the frequent coincidence of rhinopharyngitis, bronchitis, and bronchopneumonia with rickets, scurvy (manifest, effaced or latent) and xerophthalmia.

From the acquired predisposing factors just considered, Professor Frontali passes to the strictly individual and family constitutional factors (exudative diathesis of Czerny, angioneuroses, endotheliopathy—studied by the rapporteur in its capillary manifestations—adenoids, allergy), which may explain certain chronic infections, with frequent recurrence of acute crises and specific manifestations without apparent reinfection by other sufferers.

These considerations concerning exudative, lymphatic and adenoid subjects hold good for subjects in whom to the congenital constitution is superadded a tubercular infection, that is to say, scrofulous subjects. Certain morbid conditions, such as convalescence following on debilitating illnesses not caused by nutritional trouble, also exert a considerable predisposing influence.

In general, the frequency and importance of upper air passage infections are, for the practitioner, a *test* of the general resistance of the child, as they are also in the case of the aged.

Starting from the foregoing observations, Professor Frontali makes the following suggestions for the prophylaxis of these diseases, suggestions aiming at (a) avoidance of contagion, and (b) opposition of the most vigorous resistance by the infantile organism to inevitable infection.

(a) Mechanical protection of the child at the point of origin of the infection, as soon as the first stages of the disease are recognized. The fountain-head of the infection may be the mother or the nurse. The question of con-

tinuing breast-feeding by the mother or nurse suffering from influenza is settled in the affirmative, due precautions being taken—contact limited to the feeding time, previous washing of the breast, use of a gauze mask. This case is, theoretically, the only one in which an adult suffering from coryza or influenza should come near an infant; but in practice it is not easy to dispense from the care of a child, healthy or sick, whether in institution or hospital, in the family circle or at school, everybody suffering from even the mildest form of rhino-pharyngitis which may give rise to influenzal infection.

However, parents, informed of the danger, can attempt to segregate the healthy child from the persons affected; they ought to know the usefulness of the gauze mask and the method of employing it. The education of teachers and of the staffs of children's institutions (especially those for babies) should lead to the adult sufferer himself, at the very outset, declaring the disease, even when it is slight (care being taken to prevent the sufferer from keeping silence through fear of consequences, such as dismissal for reasons of delicate health). Decisions taken by the director of an institution will vary with the case (for cases of afebrile coryzas in homes, creches, hospitals), the use of the gauze mask; for feverish influenzal cases, cessation of service until complete cure.

In hospitals and other institutions for children, transmission from the sick child to his neighbors in adjacent cots can only be avoided by the individualization of personal effects, and by a certain distance being maintained between cots (about 4½ feet). Impermeable and transparent partitions of glass or even cellophane, about 8 feet high, are necessary. The system of individual open boxes is indispensable in every institution that receives children under 2 years.

(b) Habituation to climatic conditions: For all normal children, and more particularly for children constitutionally vasolabile, exudative, and disposed to colds, life in the open air provides excellent exercise of the mechanism charged with adapting the organism to weather variations. This treatment is to be completed by hydrotherapy, massage, active and passive movements and gymnastics from early childhood.

Climatological study, not only physical but biological and medical, of the atmospheric conditions that favor influenzal affections, is greatly to be desired. Such a study would permit us to recognize more exactly the conditions that contraindicate the going-out of children (damp cold, etc.). In this connection Professor Frontali suggests the creation of special observatories, to be attached to university pediatric clinics, and staffed by climatologists who would have a certain interest in working with pediatricians. Study of harmful conditions prevailing in closed rooms will lead to their bettering, by regulating the renewing of the air, the heating, the degree of humidity, and in the countries where it is necessary the cooling of the air.

Feeding—Breast feeding during the first year guarantees resistance to influenzal affections and their more important complications. After weaning the nutrition problem must be solved by the pediatrician and the family doctor, due regard being paid to the influence of proper feeding on the general power of resistance of the child (importance of alimentary fats rightly used, of the liposolubles A and D, and of the anti-scorbutic and anti-beriberic factors in avoiding all possibility of dysergy by avitaminosis).

To be well nourished is one of the fundamental conditions necessary for reducing influenzal attacks to a minimum. One must try to maintain this condition as far as possible by a bal-

anced, complete diet, even during illness of long duration.

Vaccino-prophylaxis—This question is at the point where a solution must be sought in connection with a solution of the etiological problem or problems. Polyvaccines (B. de Pfeiffer, pneumococcus, diplococcus catarrhalis, streptococcus) have been tried, by the rapporteur among others, with encouraging results.

Medicamental prophylaxis—(1) General—Salicylates, aspirine, pyramidon, quinine have not given, in regard to frequency of attacks or to complications, sufficiently convincing results; while treatment by iodine, arsenic, cod liver oil and sea air, in the case of exudativo-lymphatic and scrofulous subjects, are of patent utility since they help to diminish the predisposition to catarrhal affections.

(2) Local—It would be impossible to draw up a list of the topical remedies which have been proposed (nasal instillations, pharyngeal pulverizations, etc.), with a view to disinfecting, cleansing, washing, and rendering more resistant predisposed mucosa. Where such remedies have been used to prevent the diffusion of infection in a collectivity of children, the results have not been heartening. Inhalation of iodine salts is certainly indicated in lymphatic subjects predisposed to catarrh, more particularly in the second period of childhood.

General and local prophylaxis by medicaments find their use in the treatment of lymphatic and scrofulous subjects rather than in the general fight against influenzal affections of early childhood. — Prof. G. Frontali — La profilassi individuale e collettiva verso le effezioni influenzali della prima infanzia. Association Internationale de Pédiatrie Préventive (Section Médicale de l'Union Internationale de Secours aux Enfants), Troisième Conférence, Luxembourg, les 27 et 28 septembre 1933.

PUBLIC HEALTH NURSING*

The First C.W.S.A. Nursing Project in Indiana—As soon as it was announced that women would have a chance at C.W.S.A. jobs, the wideawake superintendent of schools in one of our populous counties in which there had never been a county public health nursing service sent in a project calling for 8 nurses to do school health work.

In the meantime the State Commission on Unemployment Relief responsible for the Indiana Civil Works Administration, having already received many inquiries about the employment of nurses, chiefly for public health, appointed a committee to approve nursing projects and nurses' applications for them. The executive secretary of the State Tuberculosis Association was made chairman; other members of the committee were the executive secretary of the State Nurses' Association and the Director of the State Bureau of Public Health Nursing.

The newly formed committee met at once with the newly appointed director of women's work in the State House and approved the above project calling for 8 nurses. A form of application was drawn up by the chairman of the nursing committee, which decided that a nurse was not eligible for a C.W.S.A. position unless she was registered in Indiana or had a permit to practice nursing here pending registration. The committee was also firm in the principle that every nursing service developed should have competent nurse supervision.

With these principles in mind the assistant director of the State Bureau for

Public Health Nursing visited the county asking for the 8 nurses, to see that the plan was carried out. A competent local public health nurse was found whose economic status enabled her to be approved by the local social worker representing the State Civil Works Administration. The local registrar of the Nurses' Directory checked up on the professional qualifications of the nurse applicants with assistance from the office of the State Nurses' Association.

Within a few hours after the state had wired the county superintendent of schools who sponsored the project (which had been approved by the local County C. W. S. Administrator), 7 of the 8 nurses were on hand with their supervisor and were holding a 2-day institute to initiate them into school health work. The details of instruction for the institute had been worked out with the supervisor of nurses by the nurse from the State Bureau of Public Health Nursing, who on the day before had accompanied the supervisor and the superintendent of schools to a meeting with the officers of the local county medical society who already constituted the Medical Advisory Committee for the local Public Health Nursing Association. She was supplied with standing orders for school nurses, worked out by one of our prominent school physicians, the *Manual of Public Health Nursing* (2nd ed.) and the American Red Cross *Rural School Nursing*. Rules and regulations for the school nurses were worked out by the medical advisory committee with aforementioned standing orders to guide them.

Ways and means of equipping the

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

school nurses were worked out. It was decided that white uniforms were expensive to launder and were not suitable for public health nursing. The staff decided they would wear the regulation blue public health nurse's uniform. They bought a bolt of cloth together, and uniforms were made by members of their families or the nurses themselves. Each nurse furnished a bag of some kind and made a washable lining to hold the few bottles necessary for soap, alcohol, etc.

The following week a project was filed for two additional nurses for this county to work under the same nurse supervisor. It was approved. On December 12 the nursing supervisor wrote to the assistant director: "Our nurses went out to the schools this morning, uniforms, bags, and all. The getting ready has been real interesting and not so terribly hard, thanks to you for the splendid outlines and notations."

The following week the secretary of the State Medical Association called up saying the secretary of the Vigo County Medical Society had sent in a copy of the rules and regulations the local medical advisory committee (of which he was a member) had drawn up for the new rural public health nurses. After a conference with the Bureau of Public Health Nursing Staff, the State Secretary decided to mimeograph them and with a letter send them out to each county medical society secretary in the state.

Since so many counties were asking for public health nurses, who necessarily were unqualified for public health work and since the State C.W.S.A. Nursing Project Committee decided there should be competent nurse supervision for all nursing projects, the State Bureau of Public Health Nursing had a project approved to add 3 advisory nurses to its staff. They are all qualified public health nurses who have had county nursing experience. Each is assigned a

district of the state; each drives her own car and pays her own expenses. So far they have been gratefully received by the new nurses, their sponsors, the secretaries of the local medical societies, and the local health officers.

To date, 111 nurses have been employed in hospitals and in public health work on C.W.S.A. projects in Indiana. More are constantly being assigned as new projects come up.

Public health nurses are in demand for immunization work sponsored by the state and local medical societies and for a sanitation campaign being put on in southern Indiana. There is getting to be a scarcity of local nurses to man the nursing projects. E. F. M.

Red Cross Nurse Receives Florence Nightingale Medal—A Florence Nightingale medal, accompanied with a citation on vellum, has again been awarded to a member of the national staff of the American Red Cross, this time to Charlotte M. Heilman, R.N., assistant national director of the Red Cross public health nursing service. The award is made annually by the International Committee of the Red Cross at Geneva to graduate nurses who have won special distinction in the care of the sick and wounded in war or disaster.

It was at the meeting of the International Red Cross in London in 1907 that the idea of honoring the founder of modern nursing with a commemorative medal was first proposed. Miss Nightingale, who was then alive, was pleased to assent, and at the following International conference, held in Washington, D. C., in 1912, the plan was unanimously adopted. Although proposed by the Hungarian delegates, it was the American delegates who caused the award to be restricted to graduate nurses. At that time nursing schools were rare in Continental Europe although not in England, and were un-

known in Central Europe. Provision was then made for 6 medals to be given to nurses of outstanding achievements, the number to be increased to 12 in the event of war. However, before any awards could be made the Great War occurred.

Mrs. Heilman's services attracted international attention during the war and after. Born and educated in West Virginia, she graduated from the Johns Hopkins training school in 1908, and accepted a place in the Trudeau Sanatorium, and later became educational secretary for the Tuberculosis League of Pittsburgh. She then married an engineer whose work took them to South America. When widowed, she returned to nursing and social work at Bound Brook, N. J. When the United States entered the war in 1917, she was assigned to the American Red Cross Commission in Italy, where she served both at the front and in the hospitals in Sicily and the island of Chioggia. After the armistice she engaged in tuberculosis work in Italy, and in 1920 was transferred to Serbia for child welfare work for several months, and then to Greece with its great refugee problem. In coöperation with the Patriotic League of Greece she organized child welfare work and served as director of nursing in the American Red Cross relief of refugees that followed the burning of Smyrna. She also assisted in forming the National Society of Nurses in Greece. In recognition of her work, she was decorated by the king in public ceremonies at Athens. Her European service ended in July, 1923.

Returning to the United States, Mrs. Heilman continued with the Red Cross. Her first assignment was to Santa Domingo, where she developed an excellent program in home hygiene for

the native women. In 1925, she was assigned as nursing field representative for Florida and Georgia and gave service in the great Florida hurricane of 1926. After periods of similar service in the states of New York and Kentucky, she was transferred to the Red Cross headquarters in Washington, D. C., as assistant director of public health nursing.

When the International Red Cross Committee met last April, the greatest National Red Cross Societies put forward 35 nurses as candidates for the medal. When the credentials of all were examined an award of 28 medals was made. The American medal went to Mrs. Heilman in recognition of her work in the war and post-war periods in Europe and in disasters in the United States.

Twelve nurses connected with the American Red Cross had previously been honored with this medal. However, Mrs. Heilman was the first to receive the medal in the presence of members of the Central Committee, or central governing body of the society. This was done on December 13 at the National Red Cross headquarters in Washington.

The other Red Cross nurses to wear the Nightingale medal are: Miss Clara D. Noyes, national director of the American Red Cross nursing service, Elizabeth Gordon Fox, formerly director of the Red Cross public health nursing service, but now head of the visiting nurses of New Haven, Conn., Alma E. Foerster, Florence M. Johnson, Martha M. Russell, Helen Scott Hay, Mary E. Gladiom, Linda K. Meirs, Carrie Hall, Julia C. Stimson, Lucy Minnegerode, and Alice Fitzgerald.—Release from American Red Cross, Washington, D. C., Dec. 5, 1933.

EDUCATION AND PUBLICITY*

I HEREBY PROMISE

I hereby promise that during 1934 when I learn about a good piece of work in public health education, or see a sample of good public health education material, that I will send a postal card or brief letter of appreciation to the responsible health worker or health agency.

I promise, also, that I will write to the editor when a magazine or newspaper publishes a good article on public health.

Two Dead—One Missing—A publication widely circulated among high school teachers lists 9 sources for securing information about exhibits and other materials. Two have been out of print 2 years or longer. Mail to another comes back marked "Not here." The more one uses published lists of sources the greater the conviction that the interests of users of lists can be guarded only through confirmation of all sources except possibly references to standard texts. A copy of the full reference sent by mail would result in any needed correction of the address as well as other changes.

Judging from out-of-date references noted in recently published lists it is not safe to assume that a pamphlet published a year or two ago is now in print.

'How Much Do They Know?—"P.P.J.," speaking editorially in *Journal of the Outdoor Life*:

"There is abundant evidence that the process of education carried on through" many mediums "has had results."

And yet the average man, even one who is recognized as being well educated, when

asked to tell what he knows about tuberculosis, will give an astonishingly ignorant answer. There still remains a woeful lack of knowledge concerning these matters, and this seems to us, who work in the tuberculosis field, to be most discouraging

If, however, as all agree, knowledge gives a person the ability to make choices, how can we hope in such a vital matter as the early diagnosis of tuberculosis to get people to go to their doctors until they know the basic facts about the disease? Many people can be found who, as a result of radio and other advertising, believe implicitly in some brand of tooth paste, some food or drug designed to produce beauty and health for a mere dollar bill; but few of these people realize that every case of tuberculosis comes from another, and that there are certain well known danger signs that indicate the presence and activity of the disease.

"P.P.J." does not attempt to tell what to do about it. The answer seems to rest upon the doing of more and better educational work among both children and adults.

How Difficult Is Truth—Several years back, weeks of study and conference were needed to produce statements for an anti-diphtheria poster—statements that would be scientifically true, and at the same time clear and convincing to the parent.

Recently one of our health departments published the following:

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

A case receiving sufficient serum on the first day of illness invariably recovers.

Submitting this paragraph to our own Court of Final Resort we received the following:

The judgment of experts is that this statement is unwarranted. The best that can be said is that less than 1 per cent will die of diphtheria.

Who is right? Or, who is sufficiently right to be safe in making public statements?

Why Not Make Your Own?—Why not make and use lantern slides more freely? In staff conferences and board meetings, as well as in gatherings of supporters and of the general public, slides, even a single slide, may make a point or register a fact. And do it more quickly and more vividly than many words expressed by a speaker.

Agencies working with the schools may wish to supply slides for classroom use, or pass on information to the teachers about making their own slides. The making of slides as a classroom project is one of the newer developments in visual instruction.

Practical information for teacher or health worker is given in "Making Lantern Slides: With a Camera—Without a Camera," a 7-page memorandum issued by Social Work Publicity Council, 130 East 22d St., New York, N. Y. 6 cents.

The headings include:

Why use of slides is questioned; where slides may be used; by welfare and health agencies; in schools; coöperation with school visual education leaders; helps in making slides, including how to get simple information on use of pencils, pens, paper cut-outs, cellophane, and how to make them at no cost at all; film slides or film strips; still films; reducing weight of slides.

Advertising in the School Room?—What types of materials are acceptable and what are unacceptable as the

contribution of commercial firms who supply helps for classroom use in teaching health?

Many and fervid are the objections voiced against much of the advertising served with radio entertainment. But apparently few parents or teachers seem to question the extensive introduction of advertising into the classroom. And much of what is supposed to serve health education is predominantly the advertising of specific products.

Is education to be less carefully scrutinized than entertainment?

A State-Wide Program—One of the good pieces of work in developing well directed coöperation from lay organizations is that done by Mrs. Marie Kirwan, Committee on Tuberculosis and Health, S.C.A.A., 105 E. 22d St., New York, N. Y. The latest step is the formulation of "Suggestions as to a Health Program," issued by the New York State Federation of Home Bureaus. The material appears under: aims; county health department; prevention of communicable diseases; maternal and infant hygiene; yearly health examinations; and sources of further information.

The "Suggestions" may be secured from Mrs. Edward Eddy, College of Home Economics, Ithaca, N. Y. 10 cents.

The Latest Book on Publicity—"How to Do Publicity," by Raymond O. Mayer, contains helpful information, although it is written largely from the standpoint of national distribution of publicity. The chapter on "The County Weekly and Publicity" will help state and county workers. Its chief value to public health workers is the picture it gives of the varied forms and mediums for spreading information. The book cannot meet the promise of the jacket: "It will be valuable in solving every kind of publicity prob-

lem." But Harper and Brother, New York, N. Y., will be glad to send a copy for examination. 272 pages. \$3.00.

Complications for Readers — A state health association mentions two publications of the U. S. Office of Education at 5 cents each. The address for ordering one of them is given as U. S. Office of Education, Washington, D. C.; address for the other, Superintendent of Documents, Washington. This means writing two letters, yet both should be ordered from the Superintendent of Documents. In a second bulletin from the same source one address reads: Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. This is needlessly long. The "Government Printing Office" does print the publications, but the "Superintendent of Documents" is the selling agent for nearly all United States Government publications.

The Practice of Preventive Medicine—*The Health Examiner* is a miniature magazine, "devoted to individual preventive medicine," published by New York Academy of Medicine, 2 East 103d St., New York, N. Y. It should be a form of service by health workers to physicians to bring this journal to their attention. 10 cents an issue. *Sample copies free.*

The Dec., 1933, issue is devoted to "The Practice of Preventive Medicine by the Private Practitioner," by Iago Galdston, M.D. This is source material of value to those who write or speak on preventive practice. *Especially important are the observations on the true values of the health examination.* A foreword states that the article

. . . appeals wisely to the profession to educate the public to look upon his medical adviser as a steady mentor for every member of the family and not merely as a consultant in the emergencies of disease.

A Diet Teaching Device—"Food models in natural size and color," now available, are printed in three colors on tough cardboard, each model carrying on the back an analysis of the food values represented. The collection of 123 models supplies material for illustrating normal and abnormal diets. Duplicates are provided of such foods as milk and butter which the instructor may wish to repeat when displaying a group of meals at one time.

The reproductions are to be cut out, mounted in slots in small wooden blocks or otherwise, and displayed in any desired combination. \$3.00 a set; less in quantity.

Two posters showing groups of fresh fruits and vegetables containing 5 per cent and 10 per cent carbohydrates, respectively, are offered for those interested in abnormal diets. \$1.00 each.

An illustrated folder will be supplied by the Detroit Dairy and Food Council, 910 Stephenson Bldg., Detroit, Mich.

Hygeia, January, 1934—"The Advertising of Foods, Drugs and Cosmetics"; "The Job of Being a Parent"; "Give Your Doctor a Break"; "Courageous Fear—The Mother of Safety"; "Health Pursuits in Pictures"; "High Lights on Low Blood Pressure"; "Foot Comfort"; "Mysteries of Vision"; "Tooth Decay"; "Human Nature"; "Windows to the World of Hobbies"; "Sex Education: The Mating Period"; "When Science Came to Lost Creek"; "Healthgrams"; "Before Baby Is Two: Helping the Baby to Build Healthful Ways of Acting"; "Feminine Beautification" (Part 3); "Years of Progress in the Home"; "A Housewife Looks at the Committee on Foods: Breakfast Cereals"; "Training for Athletics and Health: Training for Track"; "The Gift a King Accepts" (a children's play); "I Want to Know: What Hap-

pens When You Breathe"; "New Books on Health"; "School and Health," including "A New Program for 1934"; "What Shall We Teach?"; "Teachers and Mothers Work Together in Studying Health"; "The School Child's Day in the Home"; "Correlating Health Examinations With Class Teaching"; "A Bibliography for Solving Health Education Problems." *Hygeia*, American Medical Association, 535 N. Dearborn St., Chicago, Ill. 25 cents. Sample free.

When as Well as Who—The hang-over of 19th century ideas is a prime obstacle to 20th century health teaching. Ideas current no longer than a decade ago are not the least of our difficulties. Outmoded printed matter embalms outmoded ideas as to health and hygiene. Sales resulting from printed advertising issued years ago are reported in advertising journals.

There is no time limit to the selling life of an advertisement. Is it likely that all of our outmoded health education printed matter automatically fades away after a year or two?

*And yet much of our health education printed matter carries no date—*no warning signal even for the more intelligent and thoughtful. Should not all scientific matter in printed form be dated? And, therefore, all information or advice about health and hygiene? Need we list all of the reasons? Of course the date need not be conspicuous. It seems sufficient that it may be found readily and read easily.

Reprints from scientific journals and other periodicals sometimes give only volume and page numbers. The addition of dates is as an added service to the reader and student.

Education Concerning Obstetrics—*Journal of Indiana State Medical Assn.* (Dec., 1933) offers the following 11-point program:

1. Seventeen to 20 thousand women die annually in the United States of the child-bearing process.

2. Educate the laity that one-third of these are due to sepsis; one-third to toxemia; and that nearly all sepsis deaths and nearly all toxemia deaths should be prevented.

3. This should not be used in the nature of a scare, but rather as statistical facts showing what good obstetrics can do.

4. Educate men to know the importance of the childbearing process.

5. Educate women to go to the doctor early in pregnancy. Educate them to select a doctor known to give good care in obstetric cases and to go regularly to see him.

6. Educate women as to what good obstetric care means.

7. Educate them as to diet, exercise, sleep, rest, and general prenatal care.

8. Educate them as to delivery care and what constitutes good care.

9. Educate them as to good after-care.

10. Educate them that all pregnant women need good care throughout pregnancy, labor, and puerperium.

11. Educate them that the best American stock is decreasing and that motherhood should be one of woman's greatest hopes, and if the mother is properly cared for during childbearing there should be little to fear.

The Healthmobile in Germany—From Dr. W. W. Peter comes this account of the healthmobile of the Deutsches Hygiene Museum of Dresden:

The crew consists of two men. One, an expert mechanic who drives and maintains the truck, the electric lighting plant, the slide and cinema projecting machines. The other is a man who has worked for some years in the Deutsches Hygiene Museum, is able to explain all of the exhibit which is not already self explanatory, gives the lectures prepared by or under the direction of Dr. Weisbach, and attends to the business side of the work. These two men can unload the exhibit, measure off the area, set up the tent, string the electric wiring with lights, erect the partitions, set up the shelves around the booths, place the exhibit, arrange the benches, build the platform, and have the whole place ready for the first visitors in the remarkably short time of 3½ hours. Then on the last day in a place, when the last visitors leave at 10 o'clock, by 1 the next morning everything has been taken down and packed inside or under tarpaulins on the roof ready for an early

start. These two men are healthy specimens, sun-tanned, always neatly dressed and with pleasing personalities. One of them is also an amateur photographer.

On entering the tent one passes the ticket table where admission fees or previously secured tickets are surrendered. By day the inside of the tent is lighted and ventilated by flap skylights which can be pulled down in rainy weather. The rear end of the truck houses the projection apparatus. The pictures are thrown in reverse from within the truck to the screen at the very end. The screen also is shielded by canvas so that daylight projection is made possible. At the tail end of the truck is the platform with a businesslike speakers' table.

In the middle of the tent are two rows of benches without backs. There are 10 benches in a row and each bench seats 5 persons if they are not too fat. Around the sides and rear are the booths housing 10 subjects visualized. Over each booth is a strong, shielded electric light. One hundred and sixty more people can stand in the aisles and in the booths and see the speaker when a meeting is under way. Some of the booths have shelves along three sides. These are made of the packing boxes which house exhibit material. The entire enclosed area measures 15 x 25 meters.

There are 10 subjects visualized and explained by captions:

1. Protection of Life and Health, in industry and transportation with instructions on First Aid.

2. Accident Prevention in Home and Land on the Farms. Has a section on flies and mosquitoes. There is a caption reading "Kill the Flies, or They Will Kill You."

3. Prevention of Traffic Accidents in Country and Town. Has also a section on fire prevention.

4. Venereal Diseases. This booth is in the corner behind curtains on which is a sign "For Adults Only." Have a health examination before marriage. Physical and mental consequences of syphilis. Plastic models.

5. Protection of Children Against Crippling.

6. Campaign Against Communicable Diseases. Plastic models. Charts.

7. Health and Work. Illustrations of how sickness interferes with working ability. Dust. Gases. Cleanliness.

8. Milk. Its proper preparation, handling, and use.

- 9 & 10. Protection Against Air raids.

On each of the several tent poles marking also the end of each partition there is suspended a 3' x 4' glass covered box for transilluminating pictures of the human body

—the skeleton, the muscular system, the nervous system, and the circulatory system. There are also some beautiful anatomical preparations made by the Spaldeholz method showing various organs of the body—the heart, the lungs, bones, intestines, brain, etc.

The Healthmobile stays in a place for 1 to 3 days. The jumps are never too far apart. The towns are arranged on a schedule and the Burgomeisters notified. In so far as possible, Dr. Weisbach visits the officials beforehand and explains what this new thing is all about. He leaves the leaflets, What the Hygiene Auto Wants and Offers, as well as announcement posters and direction cards. The local officials do the rest. They find a suitable place, often in the market square. They notify the newspaper if there is one, the schools, and in other ways work up an interest in what is to come on a given date.

CAMPAIGNS

The liveliest of campaign bulletins (that we have seen) is *The Early Bird* ("catches the worm—and early diagnosis discovers 'The Bug'"), which happens to be the promotion bulletin for Early Diagnosis Campaign in New York State. Issued by State Charities Aid Assn., 105 East 22d St., New York, N. Y.; mimeographed, with simple but illustrative sketches.

"Diphtheria Immunization Campaign" outlines the plan for a statewide effort the first week of December, 1933, sponsored by the Indiana State Medical Assn., with the coöperation of numerous lay organizations. *Journal of I.S.M.A.*, 1021 Hume-Mansur Bldg., Indianapolis, Ind. Dec., 1933. 50 cents.

FOR REFERENCE AND EDUCATION

"Malaria," New York State Dept. of Health, Albany, N. Y. 2-page leaflet. Prevention, and if you have it.

"Organizing a Rural Preschool Conference." Reprint from *Public Health Nursing*. N.O.P.H.N., 450 7th Ave., New York, N. Y. 4 pages. 10 cents; 3 for 25 cents.

"A Study Program for School Nurses" is started in the Dec., 1933, issue of *Public Health Nursing*, 450-

7th Ave., New York, N. Y. Reprints, 10 cents for each month. The opening lesson takes up "The Nurse and the School Health Program."

"Suggestions for Reading in Public Health Nursing." Publications list of National Organization for Public Health Nursing, 450 7th Ave., New York, N. Y. 6 pages. *Free*. Classified as general, education, organization and community problems, records, supervision, tuberculosis, nursing, industrial nursing, mental hygiene, social hygiene, maternity and child health, school nursing and health education, nutrition, hourly appointment service, publicity helps and materials.

"What Builds Babies?" by Children's Bureau, Washington. Revised. Sold by Supt. of Documents, Washington, D. C. 8 pages. 5 cents. Mother's diet.

"What Science Knows About Cancer," by E. C. Cutler, and "Progress Against Cancer," by Ludvig Hektoen. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. Reprints from *Hygeia*. 10 and 8 pages. 10 cents each; 5 or more copies, 8 cents each.

The following from National Society for Prevention of Blindness, 450 7th Ave., New York, N. Y., are largely reprints from *Sight-Saving Review*:

"What Can an Organization for the Blind Do in Preventing Blindness?" 19 pages. 15 cents.

"Lighting for the Conservation of Vision." 15 pages. 15 cents.

"Non-Shatterable Glass in Spectacles." 2 pages. 5 cents.

"Should Your Child Wear Glasses." From *Hygeia*. 4 pages. 5 cents.

"Eyes and Athletics." Illustrated cover; limited text; for school athletes. 3 pages. 5 cents.

"Pure Cow's Milk for Every Milk Use," by Evaporated Milk Assn., 203 N. Wabash Ave., Chicago. 4-page folder. *Free*. How e.m. may be used.

"The Pursuit of the Vitamins," by

P. B. Mann. General Baking Co., 420 Lexington Ave., New York, N. Y. 16 pages. "What the vitamins do"; nutritional chart.

BOOKS AND REPORTS

The Eugenic Predicament—By S. J. Holmes. New York: Harcourt, Brace, 1933. Price, \$2.00.

This is an interesting and authoritative, though rather pessimistic, review of the situation. The author begins with some biological preliminaries and makes his case that our race carries a heavy burden of bad heredity. He is strong in his support of the eugenicist, though recognizing that we find great diversity of opinion even in those who are firmly convinced of the fundamental necessity of work in this field. He is positive in his opinion, and correctly so, we believe, that to be well-born is to possess the greatest of all gifts, while for the ill-born there is nothing which can compensate for the lack of good heredity. He points out that we may swagger as much as we see fit about being masters of our fate and captains of our souls, but when we have drawn our allotment of genes, nothing can greatly further help us, though of course he does not decry education and training.

After laying a foundation, the book ends, as far as the text goes, with a chapter on "What Can We Do About It?" All plans for the improvement of the race come under two heads: (1) those under negative eugenics, whose aim is to eliminate bad heredity; and (2) those under positive eugenics, which is concerned with efforts to increase good heredity. This brings in the question of birth control, concerning which he holds it is quite evident that in spite of the great possibility it possesses as a means of racial improvement, it is a two-edged sword, and so far has been dysgenic. If we could breed from the best 25 per cent of our

hereditary stock, in a few generations we would have a vastly superior society than one bred from the poorest 25 per cent.

He points out further a matter which he has elaborated in one of his former books, *The Trend of the Race*, that under our present social and economic régime there is a correlation between success in life and sterility which has tended to deteriorate the race. He believes that advance can come about only by interesting people in human biology and the development of a genuine and widespread desire for race betterment. At present the eugenic prospect is not hopeful.

An appendix of 34 pages gives many of the facts upon which the opinions are based. This includes a very interesting study of identical twins as regards diseases, mental inferiority, and superior ability. At the end of the book references for each chapter are given, and a good index makes easy reference. The book is well written and can be recommended to all interested in this subject, which perforce affects all of us. The printing and make-up are excellent.

MAZÛCK P. RAVENEL

Oeuvres de Pasteur—*Pasteur Valléry-Radot*. Paris: Masson et Cie. Tome VI, xii+906 pp. 1933. Price, 160 fr.

This sixth volume of the collected works of Louis Pasteur, assembled under the able editorship of Pasteur Valléry-Radot, covers by far the most important period of this great scientist's life. It includes the subject of germ theories, of virulent communicable diseases, the virus-vaccines, and the prophylaxis of rabies. His previous

work led him along a natural path to the attack upon the causative organisms of communicable diseases.

His prevision of this route appears as early as 1859 in a manuscript note. Again in 1860 he predicts the falsity of the idea of the spontaneity of such diseases. In 1862 in a note to the Minister of Public Instruction he invites attention to the probability that the investigation of the diseases of plants and animals will lead ultimately to the solution of the infectious diseases of man. In 1863 in his memoir on putrefaction he refers to his hope that these studies may aid in the solution of those diseases which the physicians of the classic period called the putrid maladies; and a few months later he drew analogies between the diseases of wine and of man. After his solution of silkworm disease and of its mode of transmission from one generation to the next, he appealed to the Emperor for a suitable laboratory in which to carry on adequate experimental investigations on gangrene, on the viruses, and on inoculation.

At the end of 1867 he decided to turn to the domain of pathology and to devote himself to researches on the viruses, to experimental inoculations, and to the study of anthrax. In the meantime Pasteur had been elected to the Academy of Medicine and found himself actively engaged in ardent discussions of putrefaction and fermentation, in destroying the dogma of the spontaneity of disease, in convincing the physicians that spontaneous generation was in reality a chimera, and in controversies over surgical dressings.

It was not until April 30, 1877, twenty years after his first publication on fermentation, in which his method was elaborated, that he published his first memoir on infectious diseases.

From 1877 to 1885 Pasteur and his collaborators, Chamberland, Roux, and Thuillier, carried on, often coincidentally

and uninterruptedly, their researches in elaboration of his germ theory of disease and therapy based thereon. These contributions are segregated by subjects as follows: the applications of the germ theory to medicine and surgery; puerperal fever; furunculosis, and osteomyelitis; the etiology of anthrax and septicemia, and the relation of earthworms to anthrax; and virus vaccines, vaccines for fowl cholera, and for anthrax.

Pasteur's contributions to the subject of attenuation of viruses were summarized by him at the Congress at London in 1881 and at the one at Geneva in 1882. In one chapter are combined the memoirs on the vaccines of fowl cholera and anthrax, on the attenuation of and increase of virulence, notes on the results of vaccination against anthrax, the reply to Koch's criticisms, and his explanations of the miscarriages in anthrax vaccinations in Italy. The papers on variola, the plague, pleuropneumonia of cattle, the etiology and vaccine therapy for hog cholera, and his contributions on cholera, are assembled in separate chapters.

There also are found his communications on rabies to the Congress at Copenhagen in August, 1884, and to the Academy of Sciences at Paris on October 26, 1885, on the method of preventing rabies after the bite, as well as various notes of the results of anti-rabic prophylaxis.

In the last two hundred pages are included various "Documents" concerned with Pasteur's work, including those both of critics and defenders, which elucidate his ideas, and present his own part in the discussions as well as the comment aroused by the public presentation of his work. The hitherto unpublished reports of Pasteur on anthrax to the Conseil d'Hygiene are to be found here.

This volume thus contains all that

Pasteur published on infectious diseases in scientific and medical journals, and in the proceedings of scientific congresses. It closes the cycle of extraordinary activity from 1848 to 1886, in which he was led by an inflexible logic from molecular asymmetry to fermentations and thence to virulent diseases. It contains some of the greatest contributions to science and unquestionably records the greatest boon to humanity of the 19th century.

The meticulous care of the editor is exhibited not only in the accuracy of the reproduction of the original texts and their correction where this is required, but also, and especially in this volume, by the explanatory footnotes with careful citations of the pertinent references. The publishing house of Masson & Cie. has given to this and to the earlier volumes a format and a typography fitting the greatness of their contents.

CHARLES A. KOFOID

Practical Food Inspection. (2 Vols.)

Vol. I. Meat Inspection. Vol. II. Fish, Poultry and Other Foods—*By C. R. A. Martin. London: H. K. Lewis & Co., Inc., 1933. Vol. I, 312 pp. Price, \$4.00. Vol. II, 250 pp. Price, \$3.00.*

Volume I is one of the best books for the inspector which it has been our fortune to run across. Beginning with Physiology and Comparative Anatomy, enough is given of these subjects for the ordinary non-professional inspector to understand as much as he needs of the anatomy of the body and its functions. Histories of slaughter houses and methods of slaughtering are given, followed by the inspection which is necessary. This takes up the usual routine of freshness or decomposition, discoloration, etc.; and then follows a list of the diseases, bacterial and parasitic, which are liable to be found. There are a glossary and a very good index. There is one colored plate giv-

ing illustrations of swine fever and swine erysipelas. The book is abundantly illustrated, and though the drawings are somewhat crude, they are descriptive and useful.

The second follows the general plan of the first volume, giving a short description of anatomy and physiology, and the differences between fish and air breathing vertebrates. This is followed by a description of the principal food fishes, each one of which is illustrated. The section on Poultry and Game follows the same general plan. Fruits and vegetables, including canned foods, are next considered. A section of 50 pages is devoted to Milk and Milk Products. This is very good, but not applicable to our custom here in America. Next come Miscellaneous Foods, Confections, Fermented Liquors, etc., and a short section of Food Poisoning; then a chapter of 35 pages on Legal Procedure. A glossary and index complete the volume.

While both these books are written from the English standpoint, they are practical and official, and though the English methods and legal procedures differ from ours, the books can be recommended for study to all sanitary inspectors and health officers.

MAZÛCK P. RAVENEL

American Red Cross Text-Book on Home Hygiene and Care of the Sick—By Jane A. Delano. 4th ed. Philadelphia: Blakiston, 1933. 391 pp. Price, Cloth, \$1.40. Paper \$.75.

The worth of this textbook is so well established and its use so widespread that any effort to keep it up to date reaches and is appreciated by large numbers of both teachers and students. This last and fourth revision is made in accordance with the new and accepted theories in the prevention of disease and the maintenance of good health. More consideration is given to mental health

and its relation to physical health. Consideration of the newer methods of prevention and control of communicable disease have been substituted for the older less effective methods. Attention is called to the importance of the infant and preschool age in building healthy children and adults. Those responsible for this revision have done a good job in widening the scope and increasing the value of Miss Delano's original contribution to health education.

VIRGINIA A. JONES

The History of Staining—By H. J. Conn. *Published by the Book Service of the Biological Stain Commission, Geneva, N. Y., 1933. Price, \$2.00.*

This book issued under the Chairman of the Commission on Standardization of Biological Stains is interesting and helpful. It adds another debt of gratitude owed by all laboratory workers to this commission. Especially interesting are the biographies of those who were pioneers in the art of staining. This book brings to us fairly complete life histories of many whose names are known to the majority of us only through the stains which they have devised and taught us to use. It should have a place in every laboratory and in libraries.

MAZÏCK P. RAVENEL

The Modern Treatment of Syphilis—By Joseph Earle Moore, M.D. *Springfield, Ill.: Thomas, 1933. Price, \$5.00.*

Syphilis is a disease in which, perhaps more than any other, proper treatment plays a tremendous part in prevention, so that we are giving a review of this book, in spite of the fact that its title implies it is entirely clinical. However, all through the book the suppression of the disease has been considered fairly.

While the author has considered the works of others freely and used the ma-

terial obtained in other clinics, this book is based largely upon the study of the 18,000 cases handled at the Syphilis Division of the Medical Clinic at Johns Hopkins Hospital. He divides syphilographers into three groups, the first of which holds that no definite statements can be made as to preferred methods of treatment; the second, that it is worth while to describe the best methods now in use and relate the results attainable, while recognizing their imperfections; and a third which holds that the standardization of treatment for all types of syphilis is not only desirable, but available. To the middle group he claims adherence, and says justly that if perfection were awaited, one might well postpone writing indefinitely. The majority of practitioners will hold with him, and a book such as that before us is a boon to the specialist as well as to the general practitioner who meets the manifestations of syphilis in its many varied forms.

The book is absolutely modern and up to date. He describes therapeutic procedures that have proved their value in the past and the newer ones which are now being tried out and some of which are of recognized value. The author is very cautious in predicting too much of some of the new and spectacular measures, but this attitude impresses one with the dependability of his opinions.

In the clinic, on the material from which he has based his opinions, there is very close coöperation between experts and the different branches of medicine, and the patient is studied and treated from the broadest possible angle.

The sociological side of syphilis is not neglected. The chapter on Syphilis and Marriage strikes us as being eminently sound. It is a question that comes up to the general practitioner frequently, and few can give dogmatic opinions. He discusses post-marital

infection as well as marriage when one or the other party is already infected. The author believes in frankness and points out that if a patient marries with his consent, but without telling the other party of his infection, and if she subsequently becomes infected, the physician is liable to legal proceedings as well as injurious criticism. He holds also that proper treatment depends largely upon both parties knowing the situation, and tells us that divorce under such conditions is not as frequent as might be supposed.

The book is written in a most interesting fashion, shows wide study, and impresses one with its sincerity. The printing is excellent. The illustrations, though few in number, are good. Each chapter ends with a well selected bibliography. We cannot but wish that it had been printed on lighter paper. The work can be recommended unreservedly. DUDLEY A. ROBNETT

Obstetrical Nursing — *By Carolyn Conant Van Blarcom.* New York: Macmillan, 1933. 634 pp. Price, \$3.00.

Here is the third edition of an excellent textbook on the nursing care of the expectant mother, the woman in labor, the young mother and her babe. It has the added advantage of being written by a nurse who has worked with numbers of obstetricians and knows they are apt to employ different methods. She overcomes controversial matters by stating that some physicians prefer one method, others another. For instance, in the care of the nipples of the expectant mother. A physician in a recent book on the same subject says

the nipples should never be hardened: Miss Van Blarcom says there are two general methods: hardening with skin astringents and softening with ointments, and "both seem to be about equally popular." This is very helpful to a young nurse who needs to know that there are more ways than one to do things and get results.

The author is thoroughly up to date on all scientific facts, and brings out some details that other textbooks on the subject have passed over, the relation between ovulation and menstruation, for instance; and the emphasis on the need for great care on the part of the prenatal patient at the time when menstruation would occur if she were not pregnant.

The chapter on the Mental Hygiene of the Expectant Mother is unusually good. Every public health nurse should be drilled on this chapter. It gives her an insight into psychology which she can get in no other place that I know of.

The book is well arranged and follows the recently noted trend of simplification in the care of maternity patients and their infants. Yet every detail that has anything to do with the subject is treated. An interesting chapter is entitled "Community Facilities for Maternity Care." There is a history and development of the Maternity Center Association of New York together with the accomplishments of the present facilities for prenatal, maternal, and child care. There are plenty of illustrations which are modern and to the point. I recommend the book without a single reservation.

EVA F. MACDOUGALL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Changes Needed in Obstetrical Practices—"The hazards of childbirth in New York City are greater than they need be. Responsibility for reducing them rests with the medical profession." Thus concludes the recommendations for improving maternal mortality experience. If the name of the city were omitted, the quotation would be equally and generally valid.

ANON. Maternal Mortality. J.A.M.A. 101, 23:1826 (Dec. 2), 1933.

Do Food Handlers Pass on Their Colds to Us?—Fifteen Johns Hopkins apes were long kept free from respiratory infection. Then they were given food prepared by a person with a common cold. Bliss and Long report that within 48 hours 5 apes developed a coryza and 2 a moderately severe cough.

ANON. Transmission of Colds by Food. J.A.M.A. 101, 26:2054 (Dec. 23), 1933.

Preventing Tetanus with Toxoid—Experimental animal tests with tetanus toxoid showed a high degree of protection and suggest the possibility of producing human immunity against tetanus without creating the hypersensitization against horse serum which the use of tetanus antitoxin entails.

BERGY, D. H. and ETRIS, S. Tetanus Toxoid in Prophylaxis Against Tetanus. J. Prev. Med. 53, 3:531 (Nov.-Dec.), 1933.

Additional Indictments against Silica Dust—Silica is a body poison like lead; its worst effects are in the lungs through which it gains access to the body, but silica also impairs any of the functional systems of the body. Silica dust is the most widespread and insidious industrial hazard.

COLLIS, E. L. and YULE, G. U. The Mortality Experience of an Occupational Group Exposed to Silica Dust Compared with That

of the General Population and an Occupational Group Exposed to Dust Not Containing Silica. J. Indust. Hyg. 15, 6:395 (Nov.), 1933.

How to Stop Running Noses—Two relatively harmless derivatives of opium (a combination of codeine and papaverine) were found effective in treating cases of acute coryza. The drugs were not effective in treating chronic colds, coughs or influenza.

DIEHL, H. S. Medicinal Treatment of the Common Cold. J.A.M.A. 101, 26:2042 (Dec. 23), 1933.

Encephalitis' Relation to Herpes Virus—Additional evidence is reported that epidemic encephalitis is due to a neurotropic strain of the virus of herpes simplex operating under conditions of peculiar susceptibility in the patient.

GAY, F. P. and Holden, M. The Herpes Encephalitis Problem, II. J. Infect. Dis. 53, 3:287 (Nov.-Dec.), 1933.

Complications of Vaccination—This review of the status of post-vaccinal encephalitis in Holland adds not much to the store of knowledge covered in earlier articles, but it does serve to remind us how fortunate America has been to be spared. Had our native antis been given comparable facts as ammunition, they would have made the Welkin ring.

GORTER, E. Post-Vaccinal Encephalitis. J.A.M.A. 101, 24:1871 (Dec. 9), 1933.

Social Evil Raises Its Ugly Head—Recrudescence of prostitution throughout the United States during the last few years is recounted in this story of two comparable surveys of vice conditions in large cities in 1927-1923 and 1932-1933.

JOHNSON, B. and KINSIE, P. M. Prostitution in the United States. J. Social Hyg. 19, 9:467 (Dec.), 1933.

Bacteriological Prestidigitation— Though not of immediate importance to public health administrative practice perhaps, it is interesting to note that these authors find that one may clear a bacterial culture, with phage, then filter and, through an appropriate technic, recover filtrable forms from the filtrate.

KENDALL, A. I. and WALKER, A. W. Occurrence of Bacteria in the Filtrable State in Active Bacteriophage. *J. Infect. Dis.* 53, 3: 356 (Nov.-Dec.), 1933.

Nutrition Important in Childbearing— The daily diet of pregnancy should include: 1 quart of milk, 1 or 2 servings of green vegetables, 1 or 2 eggs (or yolks), some fresh fruit and cod liver oil. In addition, sea food twice a week and liver once are recommended by this British research worker. The rest of the diet will take care of itself.

MELLANBY, E. Nutrition and Childbearing. *Lancet*, 2, 21:1132 (Nov. 18), 1933.

Preventing Tubercle Infections— "These facts face us squarely with the proposition that control of tuberculosis means prevention. A satisfactory immunizing agent is not an actuality; prevention is. Employment of epidemiological measures holds the same promise for tuberculosis as it does for other communicable disease." The "facts" are that first infection is a benign condition which at any time may become a chronic disease. The immunity of first infection is of slight value. We are not justified in speaking of tuberculosis infection without disease.

MYERS, J. A. First Infection and Reinfection Types of Tuberculosis. *Am. Rev. Tuberc.* 28, 6:793 (Dec.), 1933.

Tuberculosis After-Care— Only the third of the three activities of Pap-

worth Village is familiar to many health workers. But there are in addition to the village settlement and industries a hospital for advance tuberculosis cases and a sanatorium unit for early cases.

ROLLESTON, H. Papworth: The Parent Village Settlement for Tuberculosis. *Canad. Pub. Health J.* 24, 12:555 (Dec.), 1933.

Measles Preventive Measures— Intelligent nursing in the home is the best method of treatment for measles. Immune serum should be used for delicate children under 3 years and parental blood in all severe cases. Early publicity helps prevent complications. These conclusions are from a New York State study.

SEARS, F. W. Measles in Four Central New York Counties for 1932. *New York State J. Med.* 33, 23:1381 (Dec. 1), 1933.

Syphilis Cases Can Be Found, But— "It is practical to trace sources of infection and exposures in syphilis. By these measures a larger proportion of cases are brought under observation, the period of infectiousness reduced, and the secondarily infected ratio thereby decreased." It is practical, but all too few attempts will be made to repeat this experience despite the persuasiveness of the paper.

SMITH, D. C. and BRUMFIELD, W. A., Jr. Tracing the Transmission of Syphilis. *J.A.M.A.* 101, 25:1955 (Dec. 16), 1933.

Methylene Blue and HCN— Injections of methylene blue as an antidote for cyanide poisoning, while useful when the cyanide was swallowed, were found of no benefit in experimental animals which had breathed the poisonous gas.

TRAUTMAN, J. A. Methylene Blue in the Treatment of HCN Gas Poisoning. *Pub. Health Rep.* 48, 48:1443 (Dec. 1), 1933.

NEWS FROM THE FIELD

DR. JOHN L. RICE, NEW YORK
COMMISSIONER OF HEALTH

MAYOR LaGuardia's appointment of Dr. John L. Rice as Health Commissioner of New York City is in line with his earlier statement of policy regarding the Health Department. On October 21, 1933, the Mayor is quoted in the press as having spoken in part as follows:

It is my intention to economize to the limit, at the expense of political bosses, patronage, and waste, but never at the expense of human life. . . . Since health authorities are all agreed that public health is purchasable, I propose to purchase the best there is for our city, and I intend to get it at reasonable cost, without waste or graft, and I intend to get it right away. . . . A strong, vigorous, honest Health Department, working in harmony with the hospitals and the medical profession is absolutely essential to the well-being of every citizen of New York.

It is noteworthy that Mayor La Guardia explored the field of trained public health administrators without reference to residence, and finally

selected a Commissioner from outside of his own city.

For over 10 years, Dr. Rice has been the Health Officer of New Haven. He has engaged in public health work continuously since his graduation from Johns Hopkins Medical School in 1917, serving with the Rockefeller Foundation, International Health Division, the Kentucky and New York City Departments of Health. In the summer of 1933 he was one of two health officers chosen by the Carl Schurz Foundation of the Oberlaender Trust to visit Central Europe to study public health conditions and control measures.

Dr. Rice is a member of the Executive Board and Governing Council of the Association, and Chairman of the Health Officers Section. He is also President of the Connecticut Public Health Association. Upon his retirement as Health Officer of New Haven, Dr. Rice was elected an honorary member of the New Haven Medical Society. During his administration as Health Officer of New Haven, the effec-

tiveness of the city public health program steadily improved. This city has been awarded first place for 3 years (jointly with Syracuse in 1932), among cities of 100,000 to 250,000 population, in the National Health Conservation Contest sponsored by the U. S. Chamber of Commerce and the American Public Health Association.

DR. LINSLEY R. WILLIAMS

THE tuberculosis movement is immeasurably poorer because of the death of Dr. Linsley R. Williams on January 8 after an illness of several weeks.

Dr. Williams was the third chief executive of the National Tuberculosis Association, assuming the position of managing director in the fall of 1922. For 6 years he directed the destinies of the National Association and helped very materially to shape the course of the Association along sound scientific and financial lines during that critical period.

When in 1914, Dr. Hermann M. Biggs was selected as the first Health Commissioner of the State of New York under the new public health law, he chose Dr. Williams as his deputy commissioner and chief administrative assistant.

At the outbreak of the War, Dr. Williams enlisted and served in various capacities. In 1919, he was called to succeed Dr. Livingston Farrand as director of the Rockefeller Commission on Tuberculosis in France. In this rôle, he developed French resources so effectively that it became possible to organize, wholly under French auspices, a national anti-tuberculosis movement supported by an annual sale of Christmas seals and modeled after the American plan.

In 1922 Dr. Williams accepted the unanimous call of the Board of Directors of the National Tuberculosis Association to become Managing Director,

succeeding Dr. Charles J. Hatfield. In 1928 he resigned to become director of the New York Academy of Medicine. In this position his lifelong interest in and knowledge of political and social affairs in New York City coupled with his medical background, enabled him to influence the medical destinies of the city in ways that will be felt for generations to come. To the physicians of New York he brought not only a sympathetic attitude toward their relations with the individual patient but also a keen understanding of the more advanced social position of the physician in the community. As director of the New York Academy of Medicine and as president of the New York Tuberculosis and Health Association, he was constantly being called into consultation by the medical, public health, and political authorities of the City and State of New York on matters of the greatest fundamental importance dealing with health and social welfare.

P. P. J.

DR. R. L. KAHN AWARDED 1933 SCIENCE PRIZE

THE eleventh annual award of the American Association prize of \$1,000 given by the American Association for the Advancement of Science to the author of a noteworthy paper presented at its winter meeting, was voted to Dr. Reuben L. Kahn, Member A.P.H.A., Professor of Bacteriology at the University of Michigan Medical School, for his paper "Tissue Reactions in Immunity."

During the World War, Dr. Kahn served first as lieutenant and later as captain in the United States Army Sanitary Corps. He is now a major in the Medical Reserve Corps. Since 1928 he has occupied his present position with the University of Michigan Medical School; he is also director of clinical laboratories of the University of Michigan Hospital.

PROF. SHERMAN WINS CHEMISTRY
MEDAL

PROFESSOR Henry C. Sherman, F.A.P.H.A., Mitchill Professor of Chemistry in Columbia University and internationally known for his research and discoveries in vitamins, has been chosen for the William H. Nichols Medal for 1934. This award is presented annually by the New York section of the American Chemical Society.

The medal will be presented to Professor Sherman on March 9 at a meeting of the Chemists' Club.

Established in 1902 for the purpose of stimulating original research in chemistry, the medal this year will go to Professor Sherman for his achievement in vitamin research.

Among the achievements credited to Professor Sherman in collaboration with other chemists is the development of quantitative methods for the determination of vitamins A, B, C and G, which have played a large part in the work of many laboratories upon the concentration, purification or isolation of these particular vitamins.

Professor Sherman has been engaged in research and teaching at Columbia for the last 35 years. In 1924 he was appointed Mitchill Professor of Chemistry. He is senior author of the American Chemical Society's monograph on *The Vitamins*; a research associate of the Carnegie Institution, and a member of the National Academy of Sciences.

GOVERNMENT TO MAKE SURVEY
FOR DEAF

TO determine the types of occupations for which deaf and hard-of-hearing young people can be successfully trained, and to discover employment possibilities for them under Civil Works and Public Works Administrations, is the aim of a survey launched

by the Federal Office of Education through a grant from the Civil Works Administration. This has been announced by the Assistant United States Commissioner of Education.

PERSONALS

S. S. GOLDWATER, M.D., who joined the Association in 1902 and is a Charter Fellow, has been appointed Commissioner of Hospitals of the City of New York.

R. E. WODEHOUSE, M.D., Member A.P.H.A., was recently appointed Deputy Minister of Pensions and National Health in the Canadian Government. He was formerly Executive Secretary of the Canadian Tuberculosis Association. His successor is G. J. Wherrett, M.D., M.R.C.P.

R. W. BRADSHAW, M.D., College Physician, Oberlin College, Oberlin, Ohio, was elected President of the American Student Health Association held in Chicago, December 27-28.

DR. ROBERT P. FISCHER, Member A.P.H.A., Secretary and Chief Chemist of the Board of Pharmacy of the State of New Jersey, and lecturer in Industrial Pharmacy at the Philadelphia College of Pharmacy and Science, has been elected President of the American Pharmaceutical Association for the year 1934-35.

ETIENNE TOTTI, of San Juan, Puerto Rico, member A.P.H.A., was recently appointed by the Hon. Governor Robert H. Gore as a Member of the Insular Board of Health of Puerto Rico.

DR. EUGENE L. BISHOP, Tennessee State Health Commissioner, President-Elect and Life Member A.P.H.A., has been appointed Director of Health for the Tennessee Valley Authority, according to recent newspaper reports.

Germany's Sterilization Program

W. W. PETER, M.D., DR.P.H., F.A.P.H.A.

ON January 1, 1934, Germany began to put in force a program to sterilize those of her citizens legally adjudged unfit for parenthood. A government announcement states that approximately some 400,000 are to be sterilized in a short time. In a country where law still means as much as it does, where under the present regime orders from the top reach down to the very bottom without the obstruction, delay, detraction, and dilution which minority and opposition parties contribute, yet where nothing of this kind on such a wholesale scale has ever been attempted, where considerable undercover opposition exists, this particular program which Germany has launched merits the attention of all public health workers in other countries. If the objective of eliminating parenthood by those unfit is actually achieved in a thorough but legally and scientifically fair way, Germany will be the first modern nation to have reached a goal toward which other nations are just looking, or approaching at a snail's pace. What will actually happen remains to be seen.

The enabling law on which this program is based was enacted July 14, 1933, and promulgated¹ July 25, to go into effect January 1, 1934. Only once in this law containing 18 sections is the

word "sterilization" used, and then it is in parenthesis. The favorite term often repeated is "unfruitful" (*unfruchtbar*).

The core of the law is contained in the first section. My translation has been checked by a jurist who studied in the United States. It reads:

Those hereditarily sick may be made unfruitful (sterilized) through surgical intervention when, following the experience of medical science, it may be expected with great probability that their offspring may suffer severe physical or mental inherited damages.

The hereditary sick, in the sense of this law, is a person who suffers from one of the following diseases: inborn feeble-mindedness, schizophrenia, circular insanity, hereditary epilepsy, hereditary Huntington's chorea, hereditary blindness, hereditary deafness, severe hereditary physical deformity. Further, those may be made unfruitful who suffer from severe alcoholism.

Application for this treatment may be made by the individual and will be received when it is accompanied by a certificate from a national licentiate physician attesting that the applicant has been instructed concerning the nature and the consequences of this operation. For those legally incapable of managing their own affairs, guardians, courts, legal representatives, and trustees may make application. This procedure may also be proposed by medical officers in official health organizations, and by

superintendents of hospitals, of medical institutions, of insane asylums, and of prisons on behalf of inmates.

To avoid miscarriage of justice, there are a number of important safeguards included. The most important of these is the decision of the government not to use the ordinary existing courts of the land. Instead, 1,700 Hereditary Health Courts (*Erbgesundheitsgericht*), and 27 Hereditary Health Supreme Courts were in process of establishment immediately after the law went into effect on January 1, 1934.

Each Hereditary Health Court is to articulate with the District Court in the same area. It shall comprise a district judge as the presiding officer, a medical officer, and one additional person whose qualifications are that he shall be a national licentiate physician of proved competence in hereditary health learning. For these three members of the court, alternates are to be appointed to serve when necessary. The law states that the supreme authorities of the land are to designate the court members, the alternates, the places, and the districts of both lower and higher courts.

A second safeguard in the law is that all applications must be in writing. Facts supporting the application are to be substantiated through medical opinion or otherwise. The court office is obligated to notify the medical officer of the application.

A third safeguard is that jurisdiction for the making of a decision lies with the Hereditary Health Court in the district in which the person to be made unfruitful has legal residence.

Fourth, no judge can serve as presiding officer in one of these special courts in a case where he has rendered a decision appointing guardianship, nor can a medical officer who has sponsored an application function in his other capacity as a member of the Hereditary Health Court in the same case.

Fifth, the proceedings of a Hereditary

Health Court are not public. Such a course would be a sad blow to a certain stratum of American newspaperdom.

Sixth, the Hereditary Health Court is obligated to institute necessary investigations, call and interrogate witnesses and experts. Physicians who serve as witnesses or experts are obliged by the court to divulge information without observing professional secrecy. Judicial and governmental officials are similarly compelled to give all necessary information as the court may request.

Seventh, after an unhampered decision, the verdict of the court must be signed by those who participated in the decision regardless of whether this was for or against a given application. The written decision must include the reasons on the basis of which sterilization was approved or disapproved. This decision is then transmitted to the medical officer, to the person whose sterilization was up for decision, or to this person's legal representative.

Eighth, if the court decision is in the affirmative, it remains inoperative for 1 month. During this period the same persons entitled to file an application are likewise allowed to file an objection. Thereupon the case is reviewed by the Hereditary Health Supreme Court. If no complaint is filed against the decision of the lower court in the allotted time, the decision is automatically subject to execution. The decisions of the Hereditary Health Supreme Court are final.

The Hereditary Health Supreme Court is organized on the same basis as the lower court. It articulates with the Supreme Court in that area. Its composition is a supreme court judge, a medical officer, and a physician who is qualified in hereditary health.

A ninth safeguard is that the authorized sterilization operation shall be performed only in a hospital by a national medical licentiate. The supreme state government designates the hospitals and physicians eligible for

executing court decisions. But the operation may not be performed by any physician who has participated in the court procedures in a given case. The operating physician must send a written report to the medical officer certifying that he performed the sterilization and also by what method.

Tenth, persons participating in any capacity in the proceedings of the court are obligated to maintain secrecy. Failure to do so makes the talkative person subject to an imprisonment up to 1 year, or to a money fine.

Once sterilization has been refused court authorization, reconsideration is permissible only upon the receipt of new facts.

Sterilizations not carried out in accordance with this law, as well as castration, are permissible only when a physician acts in accordance with the known rules of medical science to avert a serious danger to life or health of the patient, whose full consent must be obtained before the operation is performed.

Once the court renders a final decision ordering sterilization, it is to be performed even against the wishes of the person most concerned, and even with the help of the police authorities to whom the medical officer may apply to take the necessary steps. When other measures fail, the employment of force is permissible.

The expenses of court proceedings are to be met with state funds. The surgical operations and hospital care are to be paid by sickness insurance funds where the patient is a member, or by public welfare funds where the patient is not a member of the sickness insurance funds and is needy. In carrying out court decisions, medical and hospital fees are to be prescribed. Only the minimum schedule of expenses may be paid from state funds. Where the patient or his family require more service than this minimum affords, they must pay the difference.

This law was signed by the German Chancellor, Adolf Hitler, by the Minister of the Interior within whose jurisdiction fall matters of public health and medicine, and by the Minister of Justice. All of the important features of this law are included in this presentation.*

There is a separate law regarding the sterilization of chronic criminals which has plenty of teeth in it. To avoid confusion and achieve reasonable length to this paper, no further mention will be made of it at this time. Here we have to do primarily with hereditary diseases and their prevention as outlined in this German program. For this same reason other laws on fostering marriages and children through financial aid, land inheritance laws, civil service and racial discriminatory laws will be omitted here.

During my 6 months in Germany, in which I traveled over 10,000 kilometers in every major section of the country, it was my privilege to meet some of the leaders in the present political regime who are responsible for new undertakings in reconstruction of the social order. I did not always agree with their points of view. But they conceded this to be my privilege. Public health practices are fairly well stabilized in this country to suit German conditions and, apart from changes in personnel and in budget, are not being seriously disturbed. The one most interesting new thing is the government's racial hygiene program of which this sterilization program is but a part.

To a foreigner there are many reasons to explain why, suddenly, this government has launched such a sterilization program. A viewpoint prevails that Germans must live with themselves within their own borders for the

* Two copies of the original promulgation by the government are on file in the office of the American Public Health Association for any who wish to make an exact and personal study.

immediate future, and depend more than ever upon their own resources. These resources are much depleted. Hence the present load of socially irresponsibles are liabilities which represent a great deal of waste.

The people have acquired a state of mind accustomed to change. So many bewildering changes of one kind or another have already been introduced during the past year that another innovation does not stand out in sharp relief. Already on their way toward changes it is not such a far jump to a philosophy of life which says in effect that human breeding is not an innate right to be exercised by all adults possessing the necessary anatomical parts, but instead, a privilege to benefit the individual, the family, the community, and the state. The state has not determined who shall breed, but in this and other laws it has most definitely stated who shall not become parents, and why.

To explain the economic reasons back of this program it is not enough to say that Germany's load from the outside is the cause—reparations, government and private post-war debts, loss of colonies, and the decline of the foreign trade; nor alone to internal loads such as the long pull toward recovery from the 1923 inflation, unemployment, war and old age pensions. These are loads which other nations are carrying also.

There are other factors which point more directly to the necessity of a sterilization program. The census of June 16, 1933, showed a total population of 66,165,879.² Of this number 738,334 are handicapped as follows³:

Physically crippled	429,654
Mentally deficient	230,112
Deaf and dumb	45,376
Blind	33,192

Another category comprising 167,854 persons lists those requiring institutional care⁴:

Insane and epileptics—

302 asylums with 141,910 beds

Feeble-minded—92 asylums with 24,519 beds

Chronic alcohol

and narcotic

addicts—33 asylums with 1,425 beds

On March 31, 1932, there were 3,854,520 persons receiving public funds. Of this number there were only 40,614 war cripples listed, and 216,199 unemployed. These few quotations from the *Statistical Yearbook of Germany for 1933* give some indication of the weight of the internal load the German social order is required to carry.

Under these circumstances it is no wonder that the German government is trying to discover ways to lighten the load. To one who lives here for some time, such a sterilization program is a logical thing.

On the one hand the government is bending every effort to organize the 1,700 lower and 27 upper Hereditary Health Courts. On the other, it engages in widespread, varied, concentrated propaganda. Under the direction of the German Medical Society, 17 special films are in preparation. Other films have already been prepared and shown. Special magazines dealing with the entire race hygiene problem have been founded with government aid. There have been a number of special conferences called by the government for physicians. At the one I attended 498 physicians paid 5 marks each for registration fees for the 3-day session. We sat from 9 in the morning till 1 or after in the afternoon, and then after lunch were taken to visit hospitals and asylums where cases were presented and discussed. At another medical congress of the same kind the course lasted for 7 days, cost 25 marks registration fee, and so many physicians enrolled that the list had to be closed. Such training schools are being operated all over the country with great success except in the strongly Catholic areas.

An example of government sponsored newspaper propaganda is the following account which was sent out from Berlin and appeared in different parts of the country⁵:

On January 1, the law to prevent hereditary sick progeny comes into force. In the entire country by January 1, there will be established 1,700 Hereditary Health Courts and 27 hereditary health high courts.

Scientific investigations have been under way to determine the number of those who within a short period of time must undergo sterilization. These estimate the number to be around 400,000, distributed among the 9 diseases which the law defines as hereditary. The larger portion, in fact, one-half, are those suffering from inborn feeble-mindedness. This approximation of 400,000 is about equally divided between males and females.

Also over the costs of making a person unfruitful there is information available. In the course of time these will be lessened very greatly while experience in this direction accumulates. Today one estimates the cost of an operation on a male to be about 20 marks. It is so simple to carry out that the man need stay on his back only 4 days. Calculating on the basis of 200,000 males, the total cost will be about 4,000,000 marks. Somewhat more ceremonious is the operation on a female. She requires at least 8 days in a hospital and an expenditure per head of approximately 50 marks; so that the sterilization of 200,000 females will cost 10,000,000 marks.

These 14,000,000 marks constitute a special burden in the first years. But the investment provides such rich interest as no other capital has ever returned. Professor Lenz has calculated that the very least the hereditary sick are costing annually is 350 million marks. Friedrich Murgdörfer comes to an amount of not more than 1 million marks difference. Measured in these figures the expenditure of 14 million marks is entirely insignificant. After 10, 20, or 30 years it is certain that the yearly expenditures of hundreds of millions of marks for the hereditary sick will decrease markedly. Providing the money will be in the greater part through the carriers of social insurance.

The opposition voiced thus far has centered largely around Catholic church influence. This influence flows through many church organization channels both inside and outside Germany. Open opposition can no longer be voiced by the Catholic party, for this Centrum party in common with all others has been suppressed. Neither the Catholic church nor the German Government is inclined to yield. The only way out may be the adoption of the proposal now under discussion whereby this church as such will assume full and exclusive responsibility for the care of those of its members who come within the purview of this law and should be sterilized. Then comes the question of how far institutionalizing these unsterilized hereditary sick should go to safeguard the communities in which they live. No answer has as yet been found to that question.

Since this law was enacted the customary leaves of absence for inmates under institutional care for the mentally sick have been withdrawn lest undesirable impregnations occur. The law will be applied on a wide scale first in asylums among those ready to be discharged, and among the feeble-minded.

In March when I pass through Germany on my return from the Balkans I shall renew some of my present contacts to secure further information on what Germany's experience has been since the law went into effect.

Practical Limitations in the Attempt to Control Enteric Disease by the Examination of Specimens Collected Without Regard to Clinical History or Epidemiological Evidence*

RUTH GILBERT, M.D., F.A.P.H.A., AND MARION B. COLEMAN
*Division of Laboratories and Research, New York State Department of Health,
Albany, N. Y.*

THE attempt to control enteric diseases through the examination of specimens collected as a routine procedure, without selection, from all food handlers or persons engaged in other occupations in which the carrier condition might render them a menace, seems in the light of our experience to be inadvisable. The findings do not justify either the work or the expense.

A study of specimens of feces and urine from food handlers in a number of state hospitals in 1924 and 1925, after outbreaks of typhoid fever had occurred in two of them, illustrates this point. Cases of typhoid fever had been reported within a period of a year or two in all of the hospitals from which specimens were received, with two exceptions. The findings in the specimens from these two hospitals are of particular interest. From one, 116 specimens were submitted from 53 food handlers, and no carriers of *B. typhosus* or *B. paratyphosus* were found. From the other, 2,053 specimens were sub-

mitted from 813 food handlers. Two carriers of *B. typhosus* and 1 carrier of *B. paratyphosus* B were found. *B. typhosus* was isolated from 1 specimen from another individual, but 14 other specimens from this person were not found to contain *B. typhosus*. If the first specimen was authentic, this particular food handler was probably recovering from an infection which had been unrecognized.

From the two hospitals mentioned, 2,169 specimens from 866 food handlers were examined and 3 carriers were found. Thus, the average number of specimens examined in discovering 1 carrier was 723. Assuming the cost of examining a specimen for *B. typhosus* to be about \$2 when large numbers of specimens are handled, the finding of 1 carrier under the conditions mentioned required the expenditure of about \$1,500.

In the examination of 6,269 specimens from 3,583 food handlers in the institutions where epidemics of typhoid fever were occurring or from which cases of typhoid fever had been reported fairly recently, *B. typhosus* was found in specimens from 47 individuals and *B. paratyphosus* A or B in those from

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

3 others. In 18 instances, these microorganisms were isolated from only 1 specimen, which would suggest that the individuals from whom they were submitted may have been recovering from an infection. Thus, even when cases of typhoid fever are occurring in institutions, the examination of large numbers of specimens is required in order to discover the typhoid carriers among the food handlers, if epidemiological and other factors are not considered.

A false sense of security may result from the examination of a specimen or two submitted from each food handler, since every carrier of *B. typhosus* would not be discovered by this procedure. Even when a number of plates are used in the study and a most careful search is made, *B. typhosus* may be found in only a relatively small percentage of the fecal specimens obtained from some typhoid carriers.

The study of environmental factors, careful history-taking, and the submission of a series of specimens of feces and urine, or preferably a specimen of duodenal contents from food handlers who have had enteric disease, colitis, cholecystitis, etc., or whose immediate associates have had typhoid or paratyphoid fever, would probably result in the detection of most carriers of typhoid or paratyphoid bacilli among them. Of course, there are exceptions. When cases of enteric disease have occurred among patrons of a restaurant or on a milk route, series of specimens from all the food handlers concerned

should be examined if the carrier is not found among those with suggestive histories.

Despite the fact that unrecognized cases occur, probably one of the best means of approaching the problem is by studying specimens from patients who are convalescing from typhoid fever or allied infections, in order to detect the ones who will become carriers. Since the submission of specimens from persons who have recovered from typhoid fever has been required by the New York State Sanitary Code, no cases of the disease, as far as the authors are aware, have been traced to an individual who has been released after fulfillment of the requirements.

In order to avoid the fruitless expenditure of time and materials in the examination of large numbers of specimens that have been collected without discrimination from various groups of individuals, the relative futility and excessive cost of such work should be explained to members of county medical societies and health officials. The same amount of money would yield vastly greater returns if expended in the pasteurization of products wherever possible, the improvement of sanitary facilities, the provision of training in personal hygiene, the removal from work and the treatment of food handlers who are obviously ill, the careful study of epidemiological factors, and the examination of series of specimens from individuals whose history or clinical manifestations warrant it.

Protein, Minerals and Vitamins of Evaporated Milk

FRANK E. RICE, PH.D.

Executive Secretary, Evaporated Milk Association, Chicago, Ill.

IN July, 1929, there appeared in this JOURNAL one of the first discussions of the nutritive value of evaporated milk.¹ Since that date, many of the statements about this food, which were then based on a limited number of researches, have been verified by a large group of experiments, both laboratory and clinical. Per capita consumption of evaporated milk has increased from 11.3 lb. to 12.5 lb. The national demand has grown by 189,600,000 lb. to an annual use of more than 1,560,000,000 lb.

If this rapid advance in consumer acceptance seems striking, so to a greater extent is the change in professional opinion in the last decade. In 1923, one of the government agencies warned that "evaporated milk may be used in emergencies for a short time only." In July, 1933, the Department of Agriculture said, "Evaporated milk is as valuable as fresh milk for food preparation."²

Notwithstanding the plenitude of such unequivocal comment, however, and although evaporated milk is considered a staple article of diet by millions of people, "certain persons cling to the belief that it will not be many years before investigators will discover it to be harmful. Many doctors are prejudiced against its use, while dietitians have been known to criticise adversely projects in low cost diets because it was used exclusively."³ And, it might be added, even though the U.

S. Public Health Service has declared that "children fed pasteurized, or other heated milk, thrive as well as children fed raw milk, and contract certain communicable diseases less frequently."⁴ It is believed that the objections to evaporated milk still heard are conscientious and sincere, and are to some extent due to recency of much of our knowledge of the nutritional value of this food.

The early work of Marriott⁵ and Brennemann⁶ on evaporated milk in infant feeding formulae is widely known; but these workers, from the nature of their problem, stressed the protein characteristics more than mineral and vitamin content. Their papers were submitted before the conclusive findings of the latter were known. They are comparatively new, and have not had as yet an extensive circulation.

The general need has been for a review of *all* the known facts concerning the nutritive value of evaporated milk, in relation to each other. A résumé of that character is the purpose here.

PROTEIN

In March, 1929, Marriott and Schoenthal⁵ stated that

. . . the heating of the milk (during sterilization) brings about certain changes in its chemical, physico-chemical and physical properties. The casein undergoes alteration so that when subsequently subjected to coagulation by rennin or acid, a curd is formed which has much finer texture than that from raw milk. . . . There are good reasons for supposing that a fine curd from milk used

for infant feeding is desirable. . . . The known qualities of evaporated milk—its sterility, its ready digestibility and uniformity of composition—are distinct advantages which recommend it for general use as milk for infants.

The ensuing years brought concurring opinions from Brennemann,⁶ Nicholson,⁷ Kerley,⁸ Reiss,⁹ Dennett and Craig,¹⁰ Sauer,¹¹ Kositzka,¹² and numerous others. Altogether since 1929, 2,700 infants have been studied in evaporated milk experiments.¹³ Kositzka states:

From our own observations on weight increases, we conclude that in the early months of the infant's life, unsweetened evaporated milk has certain advantages in infant feeding. . . . From the standpoint of economy, availability, sterility, uniformity of composition, and easy digestibility, unsweetened evaporated milk has decided advantages over bottled cow's milk in infant feeding.

Nicholson and Reiss both reported the successful use of lemon juice as an acidifier and antiscorbutic agent in the preparation of evaporated milk formulae. Hill¹⁴ has recently stated that the digestibility of cow's milk is inversely proportional to the curd tension. The curd tension of evaporated milk is 3 grams, as compared with a considerably higher value for raw milk.^{10, 14} The White House Conference on Child Health and Protection declared: "It (evaporated milk) is an economical food and on account of its many advantages bids fair to be one of the most extensively used infant foods of today."²³

MINERALS

The calcium, phosphorus, and nitrogen availability (findings on the latter element tying into the foregoing discussion) have been determined by Willard and Blunt,¹⁵ Kramer, Latzke and Shaw,¹⁶ and Jeans and Stearns.¹⁷ The first two groups of researchers studied both children and adults, concluding that evaporated milk, on a comparative basis with other forms of cow's milk, can be given a very high

rating in the ease of utilization of those elements. The last named experimenters, following an observation of 9 male infants, reported that

. . . dentition was early, the infants averaging 6 teeth erupted at 40 weeks. The physical development, as indicated by sitting and other performance, was very good. . . . The growth in length and weight was excellent and exceeded standard rates of growth and the rate of the average male infant of Iowa . . . the retentions of nitrogen, calcium, and phosphorus were high . . . early carpal ossification, rapid growth in body length, and the absence of clinical or chemical evidence of rickets are considered evidences of good bone growth.

To round out the mineral picture, Lewis and Stein¹⁸ have shown that "the feeding of evaporated milk to normal rats produces a fall in hemoglobin without the corresponding drop in the erythrocyte count that occurs when raw milk is the sole article of diet." This phenomenon they attribute to the presence in evaporated milk of a trace of copper, which retards the development of nutritional anemia caused by the low iron content of milk.

VITAMINS

On vitamins A and D in evaporated milk, we may examine the unpublished findings of Farmer and Lemkau. Both vitamins, these workers found, are present in evaporated milk to the same extent as in the original milk, unaffected by evaporation, homogenization, sterilization, or storage. Barnes,¹⁹ who observed a group of infants, reached the identical conclusion concerning vitamin D.

Koch and Samuels,²⁰ and Todhunter,²¹ found vitamin G present to the same extent as in the original milk. Koch and Samuels reported a loss of about one-fifth to one-sixth of vitamin B in the evaporation process. As milk is not an important source of vitamin B, and since other foods containing it should be given, this loss is not significant. The same holds true with

reference to vitamin C. While heating no doubt eliminates a large part of it, milk, even in its original state, has never been considered, quantitatively, a good source of this vitamin. In fact, no infant or child is well fed without the addition of an antiscorbutic.

It is a correct assertion that in the vitamins of which milk is a good source, associated with growth, protection against respiratory infection, and pellagra, evaporated milk is completely dependable.

STERILITY

Deming and Davis²² undertook a bacteriological study to determine whether evaporated milk was sufficiently free from viable microorganisms to be, from the bacteriological standpoint, a safe food for infants. For the investigation these workers purchased 154 "tall" cans from the open market. From each tin of milk both anaerobic and aerobic cultures were prepared. After observing such cultures from 102 of the cans at 37° C. and from 104 of the cans at 55° C., they concluded that

... evaporated milk is not only free from pathogenic microorganisms, but may, for all practical purposes, be considered sterile.

USE IN SPECIAL CONDITIONS

Marriott and Schoenthal⁵ early stated that

... evaporated milk was especially suitable for premature infants; and, when suitably modified, was a satisfactory food for sick infants, especially those suffering from nutritional or gastrointestinal disturbances.

Their experience has been borne out by others. Poole and Cooley²⁴ indicate that prematures over 1,400 grams in weight

... thrive well when a diluted, unsweetened, evaporated milk formula, with added carbohydrate, is gradually and carefully substituted for modified breast milk. Non-acidified evaporated milk has been found satisfactory for the larger prematures and during the period of after-care in the homes.

These two workers also used evaporated milk successfully in diarrhea cases,²⁵ reporting that

... when diluted to one-half or two-thirds strength, with protein or carbohydrate additions, it proved to be a satisfactory formula for most of our patients as soon as they were able to take milk ... the evaporated milk formulae can be readily adjusted in percentage, acidity, and consistency to meet these special requirements.

Cutler²⁶ has demonstrated that the denaturing of the whey proteins lactalbumin and lactoglobulin, in the course of the sterilization of evaporated milk, render it tolerable to milk-sensitive persons. West²⁷ has said, in regard to the feeding of the marasmic baby:

A very digestible high caloric type of feeding is essential. The marasmic infant is usually intolerant to fats and sugars, and for this reason does not do well on the ordinary raw or cooked cow's milk dilutions with soluble carbohydrate additions. The easily digested unsweetened evaporated milk with additions of calcium caseinate and starch has been found to fulfil satisfactorily these requirements.

That the celiac patient can assimilate the homogenized fat of evaporated milk, was recently shown by C. V. Rice.²⁸ Unpublished work, soon to appear, indicates that from the standpoint of acidity and gastric motility, evaporated milk is useful in the treatment of duodenal and peptic ulcer, and other gastrointestinal disturbances.

FROZEN MILK

It is a curious fact that although millions of gallons of ice cream are consumed annually, and nutrition specialists recommend it as an excellent way of securing part of the daily milk quota, there are people who believe that the freezing of milk renders it dangerous to health. Palmer³³ has shown, in an experiment on albino and piebald rats, that

... standard vanilla ice cream is a valuable supplement to certain types of diet for

growth. In addition, the same ice cream alone is capable of promoting growth at a moderate rate to produce mature animals of normal or nearly normal size and weight. . . . None of the animals fed the basal no ice cream diet attained the weight of the poorest animal fed this diet mixed with one-third by weight of ice cream, although the mean consumption of total nutrients was the same. Likewise, only one animal in the basal group attained the weight of the poorest animal fed ice cream alone. . . .

Louder and Smith²⁹ fed normal evaporated milk to one group of albino rats, and frozen-thawed evaporated milk to another group. All the rats were in good physical condition at the end of the experiment, and the researchers concluded that "none of the food value of evaporated milk is destroyed by freezing, and neither is there produced any substance deleterious to health." Dr. Helen Mitchell successfully used evaporated milk that had been frozen, during a nutrition experiment in Labrador.

FLAVOR

The sweet taste of evaporated milk (which is actually an assurance of proper sterilization, and therefore safety) is something some people still find a new experience in food. Those familiar with the flavor of raw milk find it necessary to make an adjustment to the taste of pasteurized. Hollinger and Roberts³⁰ undertook to determine "the extent to which evaporated milk would be generally accepted as a beverage without any preliminary period of becoming accustomed to it . . ."

They discovered that,

. . . out of 921 individuals to whom diluted evaporated milk was served, 548, or 60 per cent, would apparently accept it without any preliminary period of learning to like it. The percentage of acceptance is greatest with younger children. . . . The ease with which the adults in this study changed their attitudes toward evaporated milk, however, indicates that prejudices can be overcome at any age provided the individual really desires to do so.

Of interest in connection with the Hollinger and Roberts work, is the report of hot school lunches prepared under the supervision of 57 teachers in 30 rural schools.³¹ These lunches, in which evaporated milk was the principal ingredient, resulted in significant gains for underweight children, a decrease in absences, better morale, and improvement in the cold lunches brought from home. A positive liking developed for the flavor of evaporated milk.

REASONABLE COST

Two other factors of importance in the school lunch program just described, were the reasonable cost of the milk supply, and its convenient keeping qualities in the sealed tin, under conditions where refrigeration was impossible. Those are the factors which have made evaporated milk of utmost need in the welfare activities now being carried on to such an enormous extent throughout the country.

The goal of optimum nutrition has not been brought nearer of attainment by this situation described by the U. S. Children's Bureau³²:

One-fifth of the children in the United States have suffered definite injury to health during the depression. . . . Malnutrition in New York City jumped from 16 per cent in 1930 to 21 per cent in 1932, among 300,000 children examined annually since 1927.

If further and more serious depredations on the national physical well-being are to be prevented, careful attention must be given to providing those on relief with an adequate milk intake. That is a principle all nutritionists are urging welfare agencies to follow. In putting it into execution they are finding that the reasonable cost of evaporated milk is a definite aid. Mixed with an equal amount of water, evaporated milk provides a whole milk for every milk use. The dairy industry has learned "how to evaporate milk

efficiently and economically,"¹ how to transport it in sealed tins without refrigeration, and how to deliver it to the consumer sans the more expensive requirements of other methods of distribution.

SUMMARY

1. A brief review has been submitted of the research on the nutritive value of evaporated milk, together with mention of the findings on its sterility, use in special conditions, food value after freezing, flavor, and cost.

2. Many workers have shown evaporated milk to be a successful food for infants, attributing this experience in large part to the soft, easily digested curd precipitated in the stomach.

3. Studies with both children and adults have demonstrated that the calcium, phosphorus, and nitrogen of evaporated milk are readily available. Evaporated milk supplies the same amounts of these elements as do other whole milks.

4. It has been established that evaporated milk supplies qualitatively and quantitatively the vitamins milk is depended upon to supply.

5. A bacteriological investigation of evaporated milk has shown it to be sterile in the sealed tin.

6. Considerable success has attended the use of evaporated milk in cases of premature birth, diarrhea, allergy, marasmus, celiac disease, and gastrointestinal disturbance.

7. It has been proved that the freezing of evaporated milk does not impair its food value, and does not produce any substance deleterious to health.

8. A study of a large group of individuals has shown that children readily accept and like the flavor of evaporated milk. Adults also quickly become accustomed to it.

9. The reasonable cost of evaporated milk is of distinct service in assuring an adequate milk intake to families affected by the economic emergency.

Need for Methods for the Bacteriological Examination of Crustacea*

ALBERT C. HUNTER, PH.D., F.A.P.H.A.

Senior Bacteriologist, Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C.

IN recent years the commercial production of cooked crustacea meats, packed in unsealed containers and shipped under refrigeration ready for consumption, has attained an important place among the seafoods industries. While statistics are not available to show over a period of years the actual production of fresh crabmeat handled and shipped as a perishable commodity, it is estimated from the known catch of hard crabs that the approximate pack in the Chesapeake Bay region alone increased from 2,000,000 lb. in 1925 to 5,200,000 lb. in 1931.¹ In that year the production of fresh crabmeat in the United States amounting to 6,779,990 lb., represented about 75 per cent of the total production of all crustacea meats sold in packages as "fresh-cooked."

Fresh crabmeat is produced commercially in 10 states on the Atlantic and Gulf Coasts and in the 3 Pacific Coast states, and in Alaska. It has become a well known article of diet and is in demand for salads, cocktails, soups, and certain cooked dishes. In addition to crabmeat other crustacea meats are produced commercially and

are shipped in cooked condition ready for consumption. In the United States and Alaska in 1931 there were produced in a fresh-cooked condition 124,052 lb. of lobster meat, 1,671,455 lb. of cooked and peeled shrimp, and an appreciable, but unknown, quantity of crayfish, or spiny lobster meat,² making a grand total of all cooked crustacea meats, including crabmeat, of nearly 9 million lb. This is no insignificant item in the American dietary.

In order to understand why there is any particular need for the development of bacteriological methods for the examination of these products it is only necessary to consider the methods of production, the opportunities for contamination, and the perishable character of the products. In preparing this type of food for the market the crustacea are cooked in retorts or open kettles. Then, after cooling and trimming, the meat is picked out by hand. Grading is based on the part of the body from which the meat is taken, and according to size of the lumps or flakes. After picking and before packing the meat may or may not be washed. The product is then weighed into cans and with no further heat treatment is packed in larger containers with crushed ice for shipment.

Special investigations with crabmeat

* Read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

have shown that the meat within the shell of the crab after cooking is sterile or nearly so. From the cooker on to the final container the product is subjected to multiple sources of contamination. Cooling of the crabs, lobsters, or crayfish, may be conducted under conditions which grossly contaminate the exterior of the shells. During picking this contamination may be transferred to the meat. Pickers too frequently are not scrupulously clean in their habits. Pans, knives, work benches, and utensils with which the meats come in contact may not be maintained in clean condition. The products also come in contact with water and ice, frequently of unknown sanitary quality. In some sections where crustacea meats are produced in quantity, toilet facilities and methods of waste disposal are primitive and crude. In some establishments it has been observed that adequate provision is not made to protect the meat from contamination with material from filthy and dangerous sources. Unless constant warfare is waged to prevent it, contamination may occur from flies, rats, and mice. Crab, lobster, and crayfish meats are handled extensively from the time of cooking until the product reaches the consumer, and there is ever present the opportunity for contamination with filth and with pathogenic bacteria. It is not the intention to imply that all crustacea meats, as produced commercially, are unclean or potentially dangerous. It is regrettable that observations in some communities have too often disclosed objectionable conditions and faulty methods, but in such instances vigorous action has been taken to bring about the desired reformation. With the proper sanitary control it is possible and practicable to produce crustacea meats free from objectionable bacteria. Following re-

cent reforms in sanitary procedures we have reason to believe that crustacea meats as now produced commercially are clean and wholesome. There is, however, need for constant bacteriological control.

It is not unreasonable to compare crustacea meats with oysters or clams that are eaten raw. In fact, the comparison might be extended to include milk. All these products offer conditions conducive to the growth of bacteria. All are handled extensively during production and are subject to contamination with pathogenic organisms, and, to some extent they are all consumed in the condition as produced without further cooking. It has been recognized for a long time that in the interest of public health and consumer protection, control of oyster, clam, and milk production involving bacteriological examination has been necessary. Standard methods for the bacteriological examination of milk and oysters have been in existence for a number of years. There is also a need for the development of a bacteriological method to ascertain whether or not fresh-cooked crustacea meats have been produced under sanitary conditions and are fit for consumption.

In its regulatory work in connection with the enforcement of the Federal Food and Drugs Act, the Food and Drug Administration in recent years has accepted the presence of fecal *B. coli* in cooked crabmeat and other cooked crustacea as evidence of filth and potential danger to health. Certain experimental work and extensive experience with these products have demonstrated a correlation between insanitary methods of production and the incidence of fecal *B. coli* in the finished product.

Institution of regulatory control of commerce in crustacea meats was begun

in an attempt to prevent the recurrence of food poisoning cases which had from time to time been reported as due to crabmeat, and to prohibit the distribution of unclean products. There were no methods for bacteriological examination of these products described in the literature. The need for such methods called for an adaptation to crustacea meat of recognized procedures for the detection of *B. coli* in other products. For some time there has been employed in the Food and Drug Administration a method of crustacea meat examination which has been satisfactory. A known amount of meat is weighed aseptically in a wide-mouth sterile bottle. To the meat is added a known amount of sterile water or salt solution, and the mixture is shaken vigorously with sterile glass beads. The resulting suspension then consists of washings of the meat containing the bacteria present on the product. Standard lactose broth is inoculated with decimal dilutions of this suspension and incubated at 37° C. Where positive presumptive tests are obtained the lactose broth cultures are streaked on plates poured with Levine's eosin-methylene blue agar. From the eosin-methylene blue agar plates typical fecal *B. coli* colonies, when present, are transferred to agar slant cultures and are later further identified and classified as to their position in the colon-aerogenes group.

This method has worked satisfactorily in the hands of the various analysts of the Food and Drug Administration in the examination of nearly 3,000 individual packages of fresh-cooked crustacea meats. The results obtained have in general correlated with the known sanitary conditions under which the meats were produced. Since the technic and media already mentioned have been found reasonably satisfactory, we have not attempted to substitute other meth-

ods or other media which are sometimes used for the detection of *B. coli* in foodstuffs. It is possible that the substitution for standard lactose broth of some other medium might result in a higher percentage of confirmations of fecal *B. coli*. Also some medium might be selected that would restrict the growth of those bacteria which interfere with the growth of colon organisms. Any of several direct plating methods using a differential medium for distinguishing members of the colon-aerogenes group might be applied to expedite the analysis. It is necessary that any method adopted must be productive of prompt results in showing whether or not fecal *B. coli* are present in crustacea meat suspected of being polluted. The product is produced, shipped, and consumed in a short period of time, and any method applicable for control purposes must be reasonably rapid. Whether the adoption of some method different from that outlined here will further expedite the work and produce equally reliable results is a subject for investigation.

It has been stated that the presence of fecal *B. coli* in crustacea meat has been accepted by the Food and Drug Administration as evidence of filth and potential danger to health. In interpreting the results of bacteriological examination of these products it has not been the practice to attach the same significance to non-fecal and intermediate strains of colon-aerogenes organisms. Just what interpretation is to be placed on the presence of members of the colon-aerogenes group not proven to be fecal in origin is an open question. The presence of such organisms may have more significance in these products, which are sterile as they start on their way through the picking house, than they would have in certain raw products. For the time

being, however, we can assume that colon-aerogenes organisms not strictly fecal in character do not indicate potential danger to health in the use of the product, although their presence may represent an undesirable contamination signifying an unclean condition. We do know that in properly conducted establishments crustacea meats can be, and are being, produced entirely free from *B. coli*. It would seem then that the presence of any fecal *B. coli* in fresh-cooked crustacea meat would constitute evidence of improper handling and filth. Standards and tolerances are always controversial topics. We are making no definite recommendation now, but if standard bacteriological methods are to be developed, some thought must be given to the question of permissible numbers of colon-aerogenes organisms, if any at all are to be permitted, in products of this kind.

In the control exerted over crustacea meat products, it has not been the practice to place a great deal of emphasis on total counts of bacteria. Nevertheless, the total counts of aerobic organisms do have a very definite significance. All the viable bacteria on the finished product are the result of contamination picked up in the preparation of the meat for shipment. Consequently, the total numbers of bacteria present are a direct index of the degree of cleanliness and expedition exercised in handling the product. It has been the procedure to plate dilutions of the suspension obtained as heretofore described using standard nutrient agar with incubation at 37° C. Better media and more appropriate incubation temperatures might be devised for these products. Any standard method developed should not overlook the significance of total counts in ascer-

taining the fitness or unfitness of crustacea meats for food purposes.

With the growth of the industry producing fresh-cooked crustacea meats various control agencies, both official and nonofficial, have a common interest in helping to produce a clean, sound, and wholesome food. Each of these agencies can, of course, develop a method of examination satisfactory to themselves, and can establish their own standards and tolerances. Such a development of diverse methods and standards of judgment would result only in confusion for the producer, and for those control agencies organized for the protection of public health and human welfare. A uniform procedure and a common basis of judgment are needed.

A statement then as to the need for methods for the bacteriological examination of crustacea can be summarized in a few brief sentences. There is an increasing production and a wide distribution of crustacea meats sold in cooked condition ready for consumption. These products are subject to contamination throughout their preparation, distribution, and sale. The nature of the contamination is such that it carries with it potential danger to the health of the consumer. The technical control of preparation and the legal control of production, distribution, and sale involve bacteriological analyses. For the accomplishment of the greatest good there should be one method of analysis acceptable to and used in common by all agencies having a part in the sanitary control of these products.

Suggested Laboratory Procedures for Use in Determining the Cause of Food Poisoning*

STEWART A. KOSER, PH.D.

Department of Hygiene and Bacteriology, University of Chicago, Chicago, Ill.

ANY consideration of procedures for determining the cause of food poisoning outbreaks must first take account of the various etiological agents concerned in these cases of illness. The term "food poisoning" is a very broad one and the illnesses included under it are caused by a variety of factors. Certain bacteria play a prominent rôle. A number of metallic compounds may produce poisoning. A few foods are inherently poisonous due to the presence of alkaloids or more obscure but perhaps related substances. The phenomenon of food allergy is occasionally encountered. Finally, there are always a number of outbreaks in which no definite causative agent can be ascertained. At times the epidemiological evidence and clinical symptoms may afford a clue to the nature of the causative agent, but at other times this information is of little assistance.

No attempt will be made to deal with chemical procedures since that problem should be referred to those especially qualified. Our chief concern here is the bacteriological examination.

When the bacteriological laboratory is asked to make an examination of suspected food we must have clearly

in mind the microorganisms which experience has shown capable of causing food poisonings. At present 3 groups have been definitely implicated, with suspicion directed toward several others. The groups for which definite evidence has been repeatedly obtained are: (1) *Clostridium botulinum*, (2) certain members of the *Salmonella* or paratyphoid group and (3) *Staphylococci*. There have been a few instances in which members of the dysentery group and streptococci appeared to be responsible and a causative rôle has been claimed for *Proteus*.

Our chief concern must be the detection of those types which have been encountered most frequently, though we should not overlook the possibility of finding some other organism which may be significant. The possibilities fall into many different bacterial groups and the organisms concerned present quite different characteristics. It seems worth while to attempt to formulate a procedure which should be effective in detecting any of them, if present, and which should not be so unduly complicated that it could not be applied by the average laboratory.

The following outline is presented, not as a standard method, but rather as a suggested procedure which it may be desirable to modify. Such an out-

* Read at the Joint Session of the Laboratory and the Food and Nutrition Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

line may have some merit if it assists those unfamiliar with this problem in the examination of suspected foodstuffs which they may be suddenly called upon to make.

LABORATORY PROCEDURE

A. First Examination—

1. Prepare a stained smear (Gram stain) directly from the foodstuff, preferably the liquid portion.

2. With a loopful of the foodstuff * streak in succession 2 agar plates, preferably a meat infusion agar. With another loopful streak 2 more plates of either Endo or eosin-methylene blue agar. Incubate for 18 to 24 hours at 37° C.

3. Inoculate a tube of broth, preferably prepared from meat infusion, with a small amount of the sample. Incubate at 37° C.

If the poisoning is suspected or definitely known to be botulism the following steps should be included:

4. Inoculate each of 3 tubes of ground meat or beef heart medium with approximately a gram or 1 c.c. of the sample. Ground lean beef, beef heart or veal is tubed with the infusion from the meat so that the layer of ground meat occupies about half of the column of the liquid. The final pH should be 7.2 to 7.6.

Immediately after inoculation 2 of the 3 tubes should be heated to 80° C. for 20 minutes to destroy vegetative cells. If an anaerobic jar is not available the 3 tubes should be layered with about 1 c.c. of sterile vaseline to form a seal. Incubation should be at 35° to 37° C.

5. A portion of the sample should also be used to test for the presence of toxin. Inject subcutaneously at least

2 guinea pigs or 2 white mice with a portion of the food. In most cases it will be necessary to centrifuge the sample before injection to get rid of gross contamination. Use 0.5 to 1.0 c.c. of the supernatant fluid for injection. Where abundant toxin formation is suspected and a sufficiently large sample is available, it is desirable to feed portions to 2 guinea pigs.

Should death of any of the animals occur, controls with antitoxin of types A and B should be included. Inject subcutaneously 2 more animals with a protective dose of type A antitoxin (usually 1 c.c. is sufficient) and an additional 2 with type B antitoxin. These 4 animals should then be injected with the foodstuff in the same way as the original 2 which did not receive antitoxin. If the antitoxic sera are not at hand, these controls should be performed as soon as they are available.

B. Subsequent Examinations—

1. Microscopic examination of the stained smear will give an idea of the relative abundance of bacteria in the product and of the morphological types present.

2. Examine the Endo or eosin-methylene blue plates for the presence of colonies resembling those of the paratyphoid, typhoid, or dysentery groups. If suspicious looking colonies are found, fish several to either Russell medium or to fermentation tubes of dextrose, lactose, and sucrose broths. If such colonies are not encountered, the plates should be incubated an additional 24 hours and reexamined. The identification of suspected intestinal pathogens requires additional procedure and is described in section C.

Examine also the nutrient agar plates and make Gram stains of several representative colonies. Note especially if staphylococcus or streptococcus col-

* If the only sample submitted is an empty jar or can, the interior should be thoroughly washed out with a few c.c. of sterile salt solution or sterile broth. The washings can then be used for the examination.

onies are present in considerable numbers.

3. The purpose of using a tube of broth is to detect by enrichment and subsequent plating any *Salmonella*, staphylococci, or other types which might have been missed by direct plating. If the steps listed under A2 and B2 have yielded no information of value, streak Endo or eosin-methylene blue plates and nutrient agar plates from this broth culture. The examination of these plates should then proceed as given under item B2.

4 and 5. (If suspected botulism) The condition of the animals which were injected under item A5 will afford preliminary evidence of the presence or absence of botulinum toxin in the food. This should now be supplemented by examination of the meat medium tubes inoculated under item A4.

These tubes should be incubated for at least 3 to 4 days. Note any macroscopic evidence of growth and prepare Gram stains from each tube. Note whether Gram-positive bacilli, with or without subterminal spores, are present. Select one or more tubes for a toxicity test similar to that carried out with the original sample under item A5. The result of this will serve to confirm that

secured with the food sample and at times it may be of great value in affording some additional information. In the event of a positive test the meat medium may be used for further purification and isolation of the culture, if this is desired.

C. Checking of Suspected Salmonella or Other Intestinal Types—

Fermentation results similar to those shown in the accompanying outline immediately raise the question whether the organism may be a member of the *Salmonella* group or one of the dysentery bacilli. Since there are many miscellaneous saprophytes which resemble the intestinal pathogens in these superficial aspects, a somewhat detailed procedure of checking is necessary. When a culture has been selected for further examination a Gram stain should be made to see whether one is dealing with a medium-size, Gram-negative, non-sporulating rod.

Salmonella Group—The members of this group which are most commonly responsible for food poisoning are *S. aertrycke*, *S. enteritidis*, and *S. cholerae-suis*. If specific agglutinating sera for these types are not immediately available, nevertheless some information

<i>Russell's medium</i> (24 hour reading)	<i>Fermentation Tubes</i>			
	<i>dextrose</i>	<i>lactose</i>	<i>sucrose</i>	
acid and gas in butt, alkaline slant	acid and gas	negative *	negative *	Similar to that produced by <i>Salmonella</i> group.
acid in butt	acid	negative	negative (or oc- casionally acid)	Similar to Flexner dysentery.
acid in butt	acid	slow acid	slow acid	Similar to Sonne dysentery.

* Incubation should be continued for at least a week or preferably 2 weeks to rule out delayed fermentation of these sugars. Delayed fermentation of lactose or sucrose is *not* typical of the *Salmonella* group.

can be obtained with sera which are usually at hand. It is suggested that agglutination tests be made with *S. schottmülleri* (paratyphoid B) serum and with *S. enteritidis* serum. While the typical *S. schottmülleri* is rarely if ever associated with food poisoning, nevertheless the *schottmülleri* serum will cause clumping of *S. aertrycke* and, to some extent, *S. cholerae-suis*. *S. enteritidis* serum is commonly quite specific. Thus the immediate application of these two sera should be useful in determining if the organism in question is one of the three *Salmonella* types most commonly associated with food poisoning.

At the same time, it is desirable that certain additional sugar fermentation tests be made, where the sugars are available. All *Salmonella* types ferment, with acid and gas production, maltose, rhamnose, mannitol, and sorbitol. Xylose is fermented by all but *S. paratyphi* (paratyphoid A) and arabinose and trehalose by all the types with the exception of *S. cholerae-suis*.

The results of the agglutination tests, together with the cultural characteristics and fermentation tests, will permit a tentative report of the presence of a member of the *Salmonella* group. The final identification of the culture will involve the application of known specific sera, together with whatever absorption tests may be necessary. The peptone-tartrate medium of Jordan and Harmon¹ will also be helpful in determining the type. Excellent summaries of the characteristics and relationships of members of the *Salmonella* group have been prepared by Jordan² and Savage³ and should be consulted in connection with the identification.

Dysentery Bacilli—While rarely encountered in cases of typical food poisoning, nevertheless a few outbreaks have been attributed to these organisms.

Members of the Flexner and Sonne subgroups appear to be implicated.^{4, 5} Here, too, positive identification can be made only after a detailed study of the physiological and serological characters of the culture in question.

Since the Flexner and Sonne types show very little cross-agglutination, it will be necessary to test the agglutination of the culture with both polyvalent Flexner serum and Sonne serum. In biochemical characteristics, it will be recalled that mannitol is fermented with acid production by both Flexner and Sonne bacilli. The chief point of biochemical differentiation is the slow acid production from lactose and sucrose brought about by the Sonne type but not by the Flexner organisms.

EXAMINATION OF FECES

Samples of excreta are often of value, particularly in those instances where the suspected foodstuff has been consumed or destroyed. If fecal specimens are taken, especial endeavor should be made to procure them during the acute stages of illness. It is believed that no detailed laboratory procedure need be given here, since the examination would follow the usual steps employed for isolation of organisms of the enteric group from feces.

EXAMINATION OF NECROPSY MATERIAL

If such material is available following acute gastrointestinal illness which might have been caused by *Salmonella* or dysentery organisms, cultures can be made from contents of the colon, spleen, and mesenteric lymph nodes. Positive cultures, which are definitely identified as *Salmonella* or dysentery types, may be of value in determining the cause of the illness. Positive cultures are usually not obtained from the blood, but where a definite *Salmonella* type has been isolated from the blood

it is often of value when taken in connection with the other findings.

In cases of botulism, toxin can sometimes be demonstrated in blood or in bowel contents by animal injection along with the use of specific antitoxins. It is necessary to centrifuge or filter bowel contents to get rid of the numerous miscellaneous bacteria which are present.

INTERPRETATION OF RESULTS

Since some outbreaks of food poisoning are due to other than bacteriological causes, perhaps the first duty of the bacteriologist is to realize that his part of the examination may at times prove to be fruitless and that he should not feel obligated to attach blame to any organism which happens to be conspicuous.

The laboratory is often asked for proof that the actual organism obtained is in reality the cause of the trouble. Unfortunately, symptoms of typical acute gastrointestinal illness can rarely, if ever, be reproduced in the ordinary laboratory animals by *feeding*. Results obtained by the *injection* of suspected cultures are open to question and should not be advanced as sole proof of an etiological rôle of the organism in question.

However, if a member of the *Salmonella* group has been isolated from the suspected food, one may rest assured that beyond reasonable doubt he has obtained the causative agent. This conclusion seems justified since these organisms are not ordinarily encountered in foodstuffs and since there is now good evidence that they are a definite cause of food poisoning. In the event that it has been possible to isolate a similar *Salmonella* type from specimens of feces or from necropsy material, additional confirmation is thereby obtained.

In the case of staphylococci one cannot be so sure of his ground. We cannot claim a causative rôle for all staphylococci and the strains associated with food poisoning outbreaks cannot be distinguished from others by any definite criterion.^{6, 7} Moreover, these types may readily gain access to a foodstuff before or during the process of collection and thus a correct interpretation of their presence is much more difficult than in the case of the *Salmonella* group. Feeding tests with the usual laboratory animals will afford no definite information and in routine laboratory work one cannot hope to repeat the feeding tests with human volunteers^{6, 7} that were originally necessary to substantiate the causative rôle of this organism. One can only rely upon the circumstantial evidence afforded by the finding of considerable numbers of staphylococci in the interior of the foodstuff.

In the case of botulism there is fortunately direct evidence in the injection and feeding of animals and the protection afforded by a specific antitoxic serum.

COMMENTS UPON THE GENERAL PROCEDURE

It must be emphasized again that the foregoing procedure is a tentative one which it may be desirable to modify. There will doubtless be considerable difference of opinion as to the different media and methods which should be employed.

The choice of the ground meat medium for detection of *Clostridium botulinum* (item A4 in the outline) will perhaps be disputed. The writer has chosen the meat medium since it is easy to prepare and has given reasonably satisfactory results in his hands. Others may prefer an infusion or a digest broth without the chopped meat.

There is still some difference of opinion as to the most suitable medium for detection of small numbers of botulinus spores. Dubovsky and Meyer⁸ reported that a beef-heart-peptic-digest-liver broth of pH 7.2–7.4 gave the most satisfactory results in their detection of botulinus spores in soil. With this medium toxic cultures were recovered when the sample contained from 10 to 100 spores. If there is time for the preparation of such a medium previous to the arrival of the sample, it might well be substituted for the ground meat medium.

In the injection of animals for demonstration of botulinum toxin, the choice of guinea pigs or white mice need not be specified, since the laboratory must often be guided by what happens to be available at the moment. It will be recalled that white mice are very sensitive to toxin on injection (though not when fed⁹) and thus small amounts of toxin may be detected. On the other hand, mice are quite susceptible to miscellaneous infections and also are injured easily during handling. For

this reason death of the mice must be interpreted with caution and positive conclusions cannot be drawn unless the results are uniform and are controlled with known antitoxic sera.

Combating Employee Illness

IN an effort to combat common colds—an illness which not only causes discomfort to its employees but also costs the company approximately \$7,800 annually in salaries paid to ill persons—the New York *Daily News* this year is offering its employees free inoculations against this winter scourge.

The medical department of the News Company holds that inoculations against colds, while far from infallible, help appreciably in 50 per cent of the cases.

Personnel records of the company show that last year the newspaper's 2,096 employees suffered 1,114 cases of

various kinds of illness. Of these, more than 20 per cent suffered from colds and related diseases. Of all the employees on the payroll in 1932, 28.6 per cent had colds or related disorders at some time during the year.

That means that nearly 600 persons were inconvenienced through this ailment and the company estimates their total salaries while absent came to \$7,800. This does not take into consideration the loss due to the lowered vitality many suffer when they return to work.—*System and Business Management*, 63, 1, Jan., 1934.

Reaching the Negro Community*

M. O. BOUSFIELD, M.D.

First Vice-President and Medical Director, Supreme Liberty Life Insurance Company, Chicago, Ill.

THE Negro furnishes one-tenth of the population of the United States, and as such his health problems should be important to public health workers. Three-quarters of these 12 million Negroes still live in southern states and the majority of them in rural areas where there are most often inadequate medical facilities for either white or black.

About 1915 there began the migration of Negroes from the rural areas and small towns to industrial centers. The importance of this shift of colored people is shown in the following changes in the 10 cities now having the largest Negro population:

	1910	1930
New York City	91,709	327,706
Chicago, Ill.	44,103	233,903
Philadelphia, Pa.	84,459	219,599
Baltimore, Md.	84,749	142,106
Washington, D. C.	94,446	132,068
New Orleans, La.	89,262	129,632
Detroit, Mich.	5,741	120,066
Birmingham, Ala.	52,505	99,077
Memphis, Tenn.	52,441	96,550
St. Louis, Mo.	43,960	93,580

Such a large and rapid movement, of a group of the population, into new living and working conditions, into crowded, segregated areas of bad housing, left a marked impression on the vital statistics of the people, from which they are now showing signs of recovery.

In the typical industrial city the Ne-

gro quarter is along the railroad, as in New Haven, Conn., or along the banks of some dirty stream as in Akron, Ohio. Again, it is in some abandoned section which is being gradually converted from residence to business, as in South Philadelphia. Occasionally, to be sure, a whole great city area, as on the south side of Chicago, or Harlem in New York City, is occupied by Negroes, but such cases are exceptional. The Hill District of Pittsburgh and the East Side in Cincinnati are rather typical instances of conditions to which Negroes are subject. Bound in, as they are, by natural or social barriers, with little opportunity for expansion, overcrowding is a certain result.

Negroes are for the most part unskilled or semi-skilled, low-paid workers, living in houses two or three generations old, which, in a recent survey, are reported to be on an average of only 16 per cent in good repair. The converted kitchenette apartment, now so prevalent in some Negro neighborhoods, in which a home built for one family, becomes the home of many families, constitutes a physical hazard of first importance, with reference to congestion, sanitary conditions, health and morals. There is lack of sunshine, fresh air, cleanliness, play space and normal recreation. There is nearly always a prevalence of influences which tend to destroy.

This concentration of Negroes in compact, segregated areas has generally had the disadvantage, in most cities,

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

of allowing to exist a great disparity of health effort between Negro and white communities. Health departments, always without sufficient funds, or personnel, to do the whole job, have concentrated their efforts in white areas where the best showing could be made before influential people, forgetting the social-educational philosophy of Professor John Dewey which says in effect that what the best and wisest wants for himself, that must the community want for all. Health officers should be interested in finding out what exists in the community for the less fortunate; put that information before the public; and secure action favorable to the elimination of these conditions. It is not popular to spend money on Negro health, and the Negro is quite unable to finance his own needs. This, coupled with racial prejudice, accounts for the generally demoralized condition of health efforts in colored neighborhoods. This applies equally to official and voluntary agencies.

Many hospitals and clinics refuse to treat colored patients and it is only with great difficulty that even tax supported medical facilities are made available for Negroes, especially in the South. This keeps the average Negro from knowing very much about the use of medical facilities for the treatment or prevention of disease. Having no place to send the Negro for medical care it is easily assumed that there is small need to carry on an active and continuous health educational campaign. This very segregation also makes it relatively easy to correct the situation, because it affords an opportunity for concentrated efforts in health work. It becomes apparent that there is a sociological problem as a part of the health picture, and that a program planned for educating colored people must also be planned for white people

to show them that in maintaining their social responsibilities and self-preservation, they must include for the Negro, not merely health education, but participation in medical facilities.

The health officer has an opportunity to do a double duty here. He may not only attack community health conditions, but he may assist in the broader aspects of race relationships. Contemplating such a double program he is likely to hesitate, but he need not, for all the elements of solution, including interracial organizations will be found to assist him.

A little preparation in the psychology of the Negro community will help. The Negro press is a good place to start. It is a large and powerful influence among colored people. There are several national Negro news distributing agencies, one of which has over 100 correspondent Negro newspapers. Interested health officers may gain enough of this preliminary information from either the local Negro press, to be found in almost every community, or by subscribing for one of the Negro weekly newspapers with a national circulation, such as *The Chicago Defender*, *The Pittsburgh Courier*, *The New York Amsterdam News*, *The Baltimore Afro American*, *The Norfolk Journal and Guide*, or others. *The Crisis* is the monthly organ of The National Association for the Advancement of Colored People. *Opportunity* is a similar monthly publication of The National Urban League. Both of these are published in New York City. All of these publications will reflect Negro opinion.

It may be necessary to write letters, or publish articles. If the word "Negro" is to be used, spell it with a capital N. Negro is a proper noun, and as such should be capitalized as much as Caucasian, Nordic, Asiatic, Indian, or the names of other races.

Negroes have waged an unceasing, and generally successful campaign, with the leading newspapers of the country for this recognition. Colored or black is the correlative of white and does not demand this treatment.

It is well in speech making to make no reference to the race question. Leave out former experiences with colored people, forego any expression of your own lack of prejudice and omit the "darky" story in dialect. Make your talk as you would in any other neighborhood, illustrating it if possible with statistics especially related to the Negro. In every community certain amenities and certain standards arise to plague the uninitiated, and somehow these few points have gained fame among colored people as being the common errors of white speakers. These points may seem unimportant to you, but the fact that they are important to the Negro should be sufficient to cause you to give them consideration.

Having got this far, let us proceed to look for a contact point within the community itself. The Negro community is not unorganized. There will be leaders and pseudo-leaders. There will also be the usual proportion of fools, objectors, politicians, ambitious self-seekers and obstructionists. In this you will unfortunately recognize a normal condition for any community. But there will also be intelligent, earnest, unselfish, racial-minded leadership too. Naturally, it is important to make the right contact. Begin with your Council of Social Agencies which will very likely be able to point out a trained social worker of color who will be an invaluable guide. A list of the available agencies for your assistance will always run into a score or so in number. Last year in Chicago we had about 75 coöperating organizations during our observance of National Negro Health

Week. Some of the principal agencies follow.

A Negro medical society which often is made up of the physicians, dentists and pharmacists, combined into one organization. If there is a colored hospital in the community it will of course be of inestimable help. There is great interest in the development of these colored hospitals and, with their out patient, and often social service departments, they are invaluable, especially in follow-up work after a campaign involving physical examinations or treatment. In addition, the following agencies should be sought:

- The Colored Press
- Colored Public Health Workers, including nurses
- Negro Health Week organization
- Social Service organizations with qualified, trained, experienced workers in charge, such as,
 1. The Urban League
 2. The Young Men's Christian Association
 3. The Young Women's Christian Association
 4. The Community Center
 5. Phyllis Wheatley Homes
- Negro Business League
- Negro Life Insurance Companies with their managers and agents
- Churches and Church organizations
- Interracial Commission
- Fraternal groups
- Women's clubs
- Study clubs
- Political organizations
- Neighborhood clubs
- Industrial workers' groups
- Social clubs
- Schools
- Parent teacher associations
- Boy Scouts
- Girl Reserves
- Barbers
- Beauty shop operators
- The neighborhood movie house

These agencies are very much like those to be found in any community and may be used in the same way.

Pioneer work in health education among Negroes has already been done by the National Negro Health Move-

ment, now under the supervision of the U. S. Public Health Service. This organization was founded by Booker T. Washington in 1915, and has developed from an early emphasis on clean-up activities, until today, in the various communities, according to their resources and leadership, it has assumed every phase of health conservation including pageants, keeping-fit methods, athletic contests, periodic health examinations and clinics for treatment. A *Health Week Bulletin* is issued and there is an annual poster contest. This annual observance is usually held in the spring at about the same time as the Early Diagnosis Campaign of the National Tuberculosis Association.

The importance of this movement lies in the fact that it has stimulated and kept alive the interest of colored people in health education. The following figures show the communities participating:

<i>Year</i>	<i>Communities Participated</i>
1925	139
1926	326
1927	405
1928	428
1929	464
1930	505

The National Negro Health Week celebration has been an effort coming from within the Negro community itself, financed from within the community, in most instances, and its direction and leadership emanating from the Negro group. Almost always it has the coöperation of the official and volunteer agencies. Of necessity it is often an indifferent job, while again often a very excellent piece of work is done. Official agencies, taking the lead in similar efforts, having improved methods of organization and greater resources could do the job infinitely better, and should.

In Chicago this work has been done in the name of a Health Council, un-

der the leadership of the Cook County Physicians Association, The Lincoln Dental Society, the Wabash Avenue Y.M.C.A. (which are colored organizations), and coöperating agencies. It is always well to get the medical men in early, and taking the lead. The secretary of the Y.M.C.A. is the active executive who pushes the work. A full-time social worker is almost imperative under the circumstances, if his organization will release him for several weeks in order that he may give the time to the immense amount of organization work preliminary to the campaign. Headquarters are maintained at the Y.M.C.A.

A thorough organization is set up with as many committees, and as many people contacted, as possible. This is done, not on the basis that all of them are going to work, but for its advertising value. The actual planning is kept in a small executive committee. Speakers are sent to churches, schools, and other public meetings several weeks in advance of the active campaign. Agents of the colored life insurance companies are called together in a mass meeting and interested in the work. They distribute pamphlets, posters and window cards advertising the meetings and the health examination clinic. They are given appointment cards for examinations to distribute on their debits, and turn these in in advance of the opening of the drive. During the 2 weeks of the campaign an effort is made to reach every church, school, and social gathering with a speaker or motion picture.

The campaign centers about a clinic for periodic health examinations at the Y.M.C.A. Motion pictures on health subjects are kept going for the waiting patients and a fine exhibit of educational posters and mechanical apparatus helps to hold their interest. The Municipal Tuberculosis Sanitarium erects a model fresh air school room and a

model sleeping porch. We use at least 6 examining rooms. Local surgical houses contribute tables, scales, test tubes, sterilizers and what-not for examination purposes. The dental equipment houses contribute 2 dental chairs and equipment for dental examinations. Many national agencies supply literature for distribution. Publicity is given by the white and colored press. In our most successful campaign in 1931, by stimulating the Health Department to examine one high school largely attended by colored students, we were able to count 3,375 babies, children, and adults who had been examined during this drive.

The management of the clinic may be of some interest. Mornings are given over to babies, afternoons to women, and evenings to men. The medical and dental societies adopt schedules for their members who volunteer their services. Each adult visits the clinic twice. On his first visit the patient's history is taken by nurses who give their services. Charts furnished by the American Medical Association are used. A specimen of urine and a blood Wassermann are taken from every applicant for examination. Provident Hospital and the Health Department take care of the laboratory work. These reports are assembled and the patient returns in a week, is examined, and advised according to his physical and laboratory findings. No treatment is given.

Another variant of this, but not so successful, was tried this year, when a complete roster of the medical and dental societies was distributed advising that during the 2 weeks of the campaign these examinations would be given free in any of the members' offices.

The advice given these patients is simple but thorough. They are told of the importance of physical examinations, that they should be repeated each year, that doctors are equipped to

make these examinations in their offices, and where impairments are found efforts are made to see that they are corrected.

The matter of awards in such educational work is important. For a number of years we gave cups and medals for the best teeth, the healthiest boy or girl, etc. A far more successful method is a certificate for every person examined. For a time we considered grading them A, B, or C, according to some loose standard of physical fitness. This was decided against and rather impressive certificates were made up like stock certificates and a gold seal placed on them. They are signed by the chairman and secretary of the Health Council and the presidents of the medical and dental societies. One year the Health Commissioner signed them, too. The certificates merely read, "This certifies that John Doe has been examined in the 1933 health examination clinic, thereby showing an interest in his physical condition, and further, he agrees to have such an examination annually. This is a real contribution to racial development."

It is surprising the amount of pride which is taken in these certificates. They are distributed at a final mass meeting and they serve the added purpose of making this meeting a success. Two nurses in white uniforms present them with all the formality of a graduation exercise. They are made out individually and rolled and placed impressively on the stage on two tables and the individuals' names are read out as they come forward. There is an attempt to give dignity and seriousness to this ceremony.

In planning a campaign among colored people you may well make your main objectives tuberculosis, for which the rate is from 2 to 6 times as high as for white; syphilis, for which there is also a high rate, and maternal and infant mortality, the rates for which

are about $2\frac{1}{2}$ times as high as for white mothers and babies.

In so far as the work done by official agencies among Negroes is concerned, the health department of the city of Detroit perhaps has been as successful as any.

In Detroit, the care of the Negro sick has been made largely the responsibility of the Negro doctor, under the direction of the city Health Department. But Detroit has an excellent Health Council in the matter of organization. So have Cleveland, Rochester, and Boston. No city, operating with a health council, surveying its field in preparation for a program, can conscientiously neglect as large a group as makes up the Negro community, ergo, form a health council, if not for the whole city, at least for the Negro community.

The foregoing should make it apparent that there are within the Negro community about the same elements for health educational efforts as are to be found in other communities. It is important to stress this point for two reasons. First, because it dispels any idea that different methods are necessary, and lets us see the problem as being one of similar design and unity. This is very important. Secondly, it also demonstrates that no new or different agencies are necessary to deal with the problem but, instead, it needs merely a broadening of the usual program to include the Negro. Perhaps one of the greatest hindrances to public health work among Negroes is the gradually failing notion that the Negro is biologically different. Often he is thought to be so different, indeed, that the public health worker just stands back and asks the question "What shall I do for the Negro?" and does nothing.

It has well been pointed out that while it might be very interesting to prove that there is a biological differ-

ence between whites and Negroes, one could really do nothing about it and it would likely have no effect upon control measures.

The whole problem involves several thousand state, county and municipal health departments. The best way to begin, is to begin. The best answer to the question of what shall I do for Negroes, is to ask the question "What have you done?" It is inconceivable, under any other circumstances, than those associated with race prejudice, that health officers can so complacently review, year after year, the unfavorable vital statistical reports of one-tenth of the population and make no special effort to correct it. In the meantime a magnificent chance for fame stands unaccepted. There is no greater opportunity for brilliant achievement, along all lines of public health work, than exists today in Negro communities. Public opinion can and should be changed. There is a moral responsibility, not being assumed even for the white population, when the black people are neglected. The great voluntary agencies need to stimulate interest in the interracial approach necessary. This is no more impossible, nor any less humanitarian, than the change of public opinion they have wrought in their various specialized fields.

Experienced public health workers attempting to visualize conditions and programs for a colored community should go back to what was accepted as being good 20 years ago and make that the starting point.

It should be realized that the Negro community today has a death rate comparable to that of the white rate of 20 years ago. Even this lagging behind is a great gain over the Negro rate of 30 years ago. Inevitably some effects of the nation-wide improvements in health conditions, though few were specifically directed toward the Negro,

have ameliorated his plight. Similarly, an improved Negro community health will lower the white rate further.

There is evident today a greater willingness than this country has ever known to experiment in social changes, under the inspired leadership of President Franklin Delano Roosevelt. The national administration stands emphatically for equality of wages, under the NRA, regardless of race, or color, despite the widespread inequalities heretofore responsible for so much of the low economic standing of the Negro which in turn contributed to low health

standards. This has a certain appositeness for the most desirable health conditions, and unless health officers plan a New Deal of equality of facilities, they must expect to be charged with plain stupidity.

Participation in these experimentations gives the greatest possible returns to the individuals so fortunately endowed as to be able to take part in the trends of the times. Such effort expended upon the Negro will come back in the form of his creative contributions to American life and in his better citizenship.

Clean Milk and Safe Milk

Clean milk is milk which has been produced and distributed with the minimum amount of extraneous contamination such as manure from the cow's udder and flanks, dust from the cowshed and dairy, and dirt from the milker's hands, utensils, and milk containers. When care is not exercised, such contamination readily occurs and dirty milk results. Dirty milk is not only esthetically objectionable but it also has poor keeping qualities, and for this reason alone reputable firms are anxious to obtain their supplies as clean as possible. Even if the dirt in milk contains no pathogenic organisms, the conditions which lead to dirty milk also

favor contamination with any pathogenic organisms which may be in a position to gain access to the milk.

It must be noted, however, that a clean milk is not by any means necessarily a safe milk. Milk obtained from a herd infected with tuberculosis or contagious abortion is never safe, no matter how cleanly it may be produced. Cleanliness of the general milk supply is desirable but cleanliness is not enough.

To insure its safety, that is to say, its freedom from pathogenic organisms, pasteurization is essential.—J. M. Hamill, M.D., *Lancet*, Dec. 30, 1933, p. 1498.

Relationship of *Shigella* Alkalescens to Other Members of the *Shigella* Group*

HENRY WELCH, PH.D., AND FRIEND LEE MICKLE, F.A.P.H.A.
Research Microbiologist, and Director, Bureau of Laboratories,
State Department of Health, Hartford, Conn.

THE organism designated by Andrewes¹ as *B. alkalescens* was considered by him and has been considered since its discovery to be non-pathogenic. Its isolation, even in diseases where no other etiological agent could be demonstrated, has been described generally as of no significance. We feel it is probably because of this, that *Shigella alkalescens* has not received the attention its presence in urine or feces justifies. In our studies of this organism during the past 8 months we have made special efforts to demonstrate it in both normal and abnormal feces and urines. The organism was always found associated with definite disease conditions.

Andrewes¹ was not able to study completely the pathogenicity of his cultures for rabbits. He states: "These experiments, few as they are, suggest that *B. alkalescens* is devoid of pathogenic power and separate it sharply from the Flexner Y group." His experiments showed further that there was no cross-agglutination with Flexner Y sera and indicated that the serological relationship of *B. alkalescens* and *B. dispar* with the Flexner Y group was remote, although he states, "There was a suggestion of some small element in

OUTLINE OF CASE REPORTS

Several strains of *Shigella alkalescens* were isolated in an outbreak of dysentery at the Brown University Infirmary, Providence, R. I. This outbreak was the second that had occurred within a few weeks. No bacteriological studies had been made of the first outbreak. In the second, several students and 2 nurses developed symptoms of dysentery.

perience have now been approved by other committees of the American Public Health Association and of the State and Provincial Health Authorities. An item on meat inspection is also included.

The committee, in its work on revision, has tried to keep pace with changing practices and new knowledge, and at the same time avoid unnecessary expansion or complication. To some degree the new items will require a change in local record keeping in order to assemble the material in the form specified. The 5-year interval between revisions is intended to avoid disturbing established routines unnecessarily.

One new feature of the *Form* is an expansion of the preliminary section relating to demographic data. Graphs have been introduced to show the distribution of death rates from specific causes in a wide array of cities. This permits a community to compare its position in these particulars with the general run of cities. A description is also given of the means of adjusting rates to a standard million of population, thus eliminating the artificial differences in rates due to different proportions of the population within age groups.

The new *Form* facilitates the recording of all services of a public health nature, including those performed by private practitioners which have been difficult to obtain heretofore, as well as those of official and voluntary agencies.

The limitations of the *Form* are discussed very frankly in the Introductory Statement. Its standards are based on professional group judgment of the day and on results now being attained in

many instances by at least a quarter of the cities whose information is available. It is not expected that a city should modify its activities solely for the purpose of increasing its score when the best judgment of the community is that the local situation dictates otherwise. The *Form* is to be considered as a useful, guiding instrument rather than as an inflexible pattern. Its aim is not to hamper but to help.

The *Form* will be used by the Field Director of the Committee on Administrative Practice when called in by cities for surveys. It will be found useful to health officers particularly in cities having over 25,000 population, and even in smaller cities. It will be extremely helpful to the Committee on Administrative Practice if health officers after scoring their cities will forward a copy of the completed *Form* to the American Public Health Association office. No publication will be made of scores without the permission of the health officer. Information as to the performance of cities with respect to the detailed items will help in keeping the central office acquainted with current practice and will also prove valuable in later revisions.

Membership of Committee includes: Earl G. Brown, M.D., A. Grant Fleming, M.D., Allen W. Freeman, M.D., Theresa Kraker Guthrie, R.N., George D. Lummis, M.D., Frank J. Osborne, L. J. Roper, M.D., John J. Sippy, M.D., Henry F. Vaughan, Dr.P.H., W. F. Walker, Dr.P.H.; representatives from Health Officers Section, Leon Banov, M.D., James Roberts, M.D., H. A. Streeter, M.D., I. F. Thompson, M.D.

Ex-officio, Carl E. Buck, Dr.P.H., Field Director, Committee on Administrative Practice.

* One out of twelve control mice survived.

Shigella alkaescens we find this organism listed as "not pathogenic." The only reference to actual attempts to demonstrate this non-pathogenicity were made by Andrewes¹ who notes that only a few animals were used for this work. The authors could find no reference to isolation of this organism from known cases of dysentery-like diseases.

In previous isolations of *Shigella alkaescens* from cases of enteric and other diseases, particularly chronic nephritis, we paid little attention to it, considering it of no etiological significance. We found however in a careful

study of such cases that in spite of definite symptoms of infection no other organism could be demonstrated to account for these symptoms.

When an outbreak of dysentery occurred in a university infirmary (reported in another section of this paper) and *Shigella alkaescens* was isolated repeatedly not only from the stools of the cases but also from an apparently healthy food handler, it appeared that we had definite indication of the pathogenicity of this organism for man. After a period of time the individuals ill with dysentery showed definite agglutinins in their blood

stream for *Shigella alkalescens*. On removal of the food handler involved no further cases developed. These findings indicated the etiological relationship of this organism to these cases.

Four additional cases are reported which were clinically diagnosed as chronic nephritis. There were no symptoms of dysentery. *Shigella alkalescens* was isolated from each. No other significant organism could be demonstrated either in catheterized urines or in stools.

From a study of the morphological characteristics of the *Shigella alkalescens* strains we found very little either in colonial or microscopic appearance that would separate them from those organisms in the dysentery group described as pathogens. In some instances there was a tendency for the colonies to show a blue pigment on eosin-methylene-blue agar after 48 hours. On the other hand, we find this to be true of some of the dysentery strains, particularly *Shigella paradysenteriae* Sonne, which the authors have reported elsewhere.

The biochemical reactions of *Shigella alkalescens* were constant over a period of 6 months and showed sufficient differences to separate it from the true Flexner and Shiga types. In our studies the production of an acid reaction by this organism in dulcitol and rhamnose and the tendency to give an alkaline reaction in litmus milk seemed sufficient to distinguish it from the other members of the *Shigella* group.

By agglutination and agglutinin absorption we were able to demonstrate a definite relationship of *Shigella alkalescens* to some members of the dysentery group (*i.e.* Harris, Hiss, Strong, Army and Shiga types) and, although this relationship is not as strong as that demonstrated previously for *Shigella dispar*, the consistency of our results on repeated trials appears

sufficient to demonstrate that a relationship exists.

The use of the Schwartzman reaction for demonstrating the relationship of organisms within a given group, such as the intestinal group, was demonstrated by one of us with Ecker⁸ in an earlier publication. We were able to show when the skin of rabbits was prepared with filtrates of intestinal bacteria such as *Escherichia coli*, *Salmonella schottmülleri*, *Salmonella enteritidis* and others that it was not possible to elicit the Schwartzman reaction by means of organisms such as the enterococcus. Since that time, however, Schwartzman⁹ has shown that it is possible to prepare the skin of rabbits with *Eberthella typhi* filtrates of high skin-preparatory potency and to elicit the reaction by means of an intravenous injection of pneumococcus filtrates. These pneumococcus filtrates had no skin-preparatory potency; *i.e.*, they were incapable of sensitizing the skin of rabbits, although possessing definite reacting potency; *i.e.*, an intravenous injection of pneumococcus filtrate would elicit a Schwartzman reaction provided the skin was prepared with a filtrate containing a high concentration of skin-preparatory factors. The fact that heterologous filtrates are capable of eliciting the Schwartzman reaction would necessarily be contraindicative of the specificity of the reaction. However, where it has been demonstrated that heterologous filtrates have been used successfully, the filtrate used in sensitizing the skin had a high concentration of skin-preparatory substances. A similar result is not possible with the ordinary filtrate.

All filtrates used in this investigation were prepared under the same conditions and concentrated as nearly as possible to the same volume *in vacuo*. Each filtrate except that of the Shiga type was shown to contain both skin-preparatory and reacting factors (Shiga

filtrate showed reacting factors only). Under these circumstances and in view of the results obtained where it was shown that various alkalescens filtrates would prepare the skin of rabbits for intravenous doses of Flexner and Shiga strains, it appears that these findings are indicative at least of a group relationship.

The results obtained in the attempts to neutralize the toxic effect of the alkalescens filtrates with Shiga anti-filtrate horse serum further augment our findings. These experiments show definitely that Shiga antifiltrate serum under the proper conditions of experimentation will neutralize the effects of the second or intravenous injections of alkalescens filtrates in the Shwartzman test in rabbits and further that the lethal action of these filtrates on mice can be destroyed by the addition, in the proper concentrations, of Shiga anti-filtrate serum.

SUMMARY AND CONCLUSIONS

1. Cases of dysentery-like diseases and others apparently caused by *Shigella alkalescens* are reported.
2. The relationship of *Shigella alkalescens* to other members of the dysentery group is demonstrated by means of agglutination, agglutinin absorption and the Shwartzman phenomenon.
3. Shiga anti-filtrate horse serum neutralizes in rabbits and mice the toxic effect of *Shigella alkalescens* filtrates.

4. This investigation indicates that *Shigella alkalescens* should be included among those organisms in the *Shigella* group capable of causing disease in man.

Examination of Fermented Foods by Laboratory Methods*

CARL S. PEDERSON, PH.D.

New York Agricultural Experiment Station, Geneva, N. Y.

THE studies of the last few years, in which a number of samples of sauerkraut have been examined, have shown that a better inspection control of fermented foods is desirable. Although this work has dealt primarily with sauerkraut, it is believed that many of the conditions observed hold true for other fermented foods, such as pickles and olives, as well as relishes prepared from various fermented vegetables; but results of definite laboratory analyses of these products have either never been published, or methods for examination have not been developed. Vinegar might be included in a broad discussion of fermented products, but methods of examination as well as regulations are quite well standardized for this product. The fermented foods here discussed include only those products that result from a lactic acid fermentation, thereby excluding vinegar, as well as beers, wines, etc.

In a report on the quality of commercial sauerkraut,¹ 8 per cent of the samples analyzed were described as unsatisfactory, while 14 per cent were described as of poor quality. This does not indicate that anyone consuming such food is in danger of suffering from poisoning, for it is known that the growth of organisms causing food poi-

sonings does not normally occur during the lactic acid fermentation. Rather, the control of this foodstuff should be considered from the standpoint of decency in packing an edible product and of protecting the consumer against fraud. Fortunately, many fermented products, such as pickles and olives, used as condiments, are packed in glass so that the consumer may see what is purchased. Sauerkraut, on the other hand, since it is inexpensive, is usually sold in cans or in bulk. Because of this and of the fact that more is known about methods of analyzing this product, the discussion will be confined to sauerkraut.

Sauerkraut is not even mentioned in some books on foods and their adulteration. Dr. W. B. White (Chief of Food Control of the U. S. Food and Drug Administration) in referring to sauerkraut in a letter states: "We have never been able to develop methods to substantiate organoleptic evidence of decomposition." In the various seizures by the Government under the Food and Drugs Act, of which there have been few, the sauerkraut has usually been described in the legal complaint as containing decomposed material.

Regulations specify that sauerkraut shall be

... the clean, sound product of characteristic flavor obtained by full fermentation, chiefly lactic, of properly prepared and shredded cabbage in the presence of not less than 2 per cent nor more than 3 per cent of salt. It contains, upon completion of the

* Read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

Approved by the Director of the New York State Agri. Exper. Sta. for publication as *Journal Paper No. 15*, October 5, 1933.

fermentation, not less than $1\frac{1}{2}$ per cent of acid expressed as lactic acid. Sauerkraut which has been rebrined in the process of canning contains not less than 1 per cent of acid.

In the analysis of over 100 samples of kraut obtained from more than 70 different packers throughout the United States, at least one-third were found by direct analyses not to conform to the above definition. It is true that this does not necessarily mean that a third of the pack was poor, since observation has shown that the kraut from the big producing sections, on the whole, is quite superior to that from sections

where the industry is not so well developed. However, there are individual companies in all sections that are careless in the preparation of their pack.

Some of the cans of kraut examined in this series of analyses were really unfit for consumption. The astonishing thing is that some canners would think of packing products that are unfit for consumption. Two samples were as green as spinach; others were pink. Some had a definitely unpleasant odor and flavor caused by secondary fermentations. One sample had a fishy flavor, and a few resembled rotten rather than fermented cabbage. The

FIGURE I
The relationship of quality to volatile acid content as found by analysis of 102 samples of canned kraut.

analyses of a few of these may be interesting.

These analyses have been based on research methods, but it is believed that they might be developed into routine control procedures. Salt was determined by direct titrations with silver nitrate, using potassium chromate as indicator; total acid by direct titration with phenolphthalein as indicator; volatile acid by steam distillation; non-volatile acid by difference; and alcohol by distillation from an alkaline solution, its oxidation to acetic acid by bichromate and steam distillation to secure the volatile acid. A supplemental microscopic examination of the juice for yeasts is often helpful if secondary fermentations are suspected.

Certain comments may be made before going further. The direct titration of salt is far more accurate than any method of sampling, it having proved to be very difficult to get a representative sample for salt determinations from vats of sauerkraut. The results secured by direct titration for total acid are from 0.1 to 0.2 per cent below the actual content of acid as obtained by extraction methods. The determination of the amount of volatile acid depends upon the acidity of the juice and the amount of steam distillate collected. In the analyses made, the juice was not acidified by addition of mineral acid, and 1,600 c.c. of distillate was collected from 500 c.c. of sauerkraut juice. Adding sulphuric acid increases slightly the amount of acid distilled over. Since lactic acid is slightly volatile, increasing the amount of distillate increases the apparent volatile acid. The alcoholic determination is fairly accurate, although in canned krauts the alcohol may have been partially volatilized before canning was completed.

These determinations are at times significant in relating the quality of

canned as well as bulk kraut to the fermentation and packing. In other words, the interpretation of the results of these analyses may be made in such a way as to reveal some of the past history of the kraut. It has been shown that in a normal fermentation of sauerkraut, a definite sequence of growth of various types of organisms takes place. The first few days of active fermentation is carried on by a group of acid and gas producing cocci, *Leuconostoc mesenteroides* Van Tieghem. They produce volatile acid, carbon dioxide, and alcohol, as well as lactic acid, and are partly responsible for the flavor of kraut. The fermentation is completed by the lactic acid producing rod *Lactobacillus cucumeris* Bergey *et al.*, and the acid and gas producing rod *Lactobacillus pentoaceticus* Fred, Peterson and Davenport. The part each of these plays in the fermentation is influenced by the amount of salt present as well as the temperature of fermentation. Using the above method of analysis, canned kraut which had been fermented normally, and properly canned, will reveal an alcohol content of from 0.1 to 0.3 per cent and a volatile acid content of from 0.2 to 0.32 per cent.

A few results are given to illustrate the way in which analyses may be interpreted (Table I).

The total acid (3rd column) is an indication of the degree of fermentation. Partially fermented kraut (*e.g.*, No. 50) shows a low total acid content, and may be slightly bitter. On the other hand, fully fermented kraut may be diluted to such an extent in canning (*e.g.*, Brand No. 93, Table I) that the acid is low. But in this case, the salt, volatile acid, and alcohol content are also diluted and therefore yield low values.

The quantity of salt originally present has a direct bearing on the texture.

TABLE I
ANALYSIS OF 6 CANS OF POOR QUALITY KRAUT CONTRASTED WITH THE ANALYSIS OF
2 CANS OF EXCELLENT KRAUT

Brand Number	Salt Per cent	Total acid as lactic acid Per cent	Volatile acid as acetic acid Per cent	Non-volatile acid as lactic acid Per cent	Ratio	Alcohol Per cent	Length of Cut*	Texture†	Color‡	Odor‡	Flavor‡	Remarks
54	3.2	1.40	0.47	0.69	0.68	0.45	L	S	P	U	U	Rotted
94	1.9	1.01	0.30	0.56	0.54	0.09	S	S	F	U	U	Fishy
93	1.6	0.62	0.11	0.46	0.22	0.09	M	S	G	F	P	Washed out, flat

3	2.2	1.30	0.21	0.99	0.21	0.23	M	F	G	E	E	Excellent
5	2.4	1.48	0.29	1.04	0.28	0.29	L	F	E	E	E	Excellent

*L=Long, M=Medium, S=Short.

†F=Firm, M=Medium, S=Soft.

‡E=Excellent, G=Good, F=Fair, P=Poor, U=Unsatisfactory.
Abnormal chemical results are indicated by bold face type.

Very frequently fermentation carried out with a low salt content is expressed by a soft textured product (*e.g.*, Table I, Brands Nos. 50 and 14). The relation of salt concentration to texture is shown in Table II. Kraut that has

a high salt content during fermentation is often discolored, sometimes pink, and usually has an abnormal flavor. Fermentation is abnormal in such cases and as a result the volatile acid may be low and the alcohol content high.

TABLE II
THE RELATION OF SALT CONCENTRATION
TO TEXTURE IN CANNED KRAUT

Number of Samples	Salt Per Cent	Percentage of samples of Soft Texture	Salt Content
5	2.8-3.4	60	Too high
28	2.2-2.5	7	
37	1.8-2.1	22	Normal
22	1.5-1.7	41	
10	0.7-1.4	80	Too Low

Volatile acid (largely acetic) is almost entirely produced by the organisms that start the fermentation process, and is present usually in quantities of about 0.25 per cent in canned kraut, and slightly higher (0.28 per cent) in bulk kraut. Considerable variation from this may be found. A volatile acid content above 0.32 per cent or below 0.20 per cent is often an indication either of an abnormal fermentation, or of a secondary fermentation. The former may be due to the fermentation having taken place at too high a temperature, to faulty salting or packing. Secondary fermentations

FIGURE II

The relationship of quality to volatile acid content as found by analysis of 184 samples of bulk kraut.

often result in the destruction of acid. The volatile acid content is often abnormal in the poor quality samples. A summary of the relationship of quality to volatile acid content in canned kraut as found from the analyses is given in Figure I. From these figures it may be noted that the volatile acid content of the good and excellent krauts all fall within 0.15 to 0.35 per cent. Samples rating poorer than this more often show analyses lower or higher. A similar summary for a number of bulk krauts is given in Figure II. The relationship is similar in this case, but the total volatile acid figures are slightly

higher, there being no dilution of acid as in canning.

Secondary fermentations of kraut are usually caused by yeasts (Figure III). They manifest themselves in a peculiar yeasty or even putrid odor. Often their action can be detected by an increased alcohol content, sometimes by the presence of yeast cells and occasionally by cocci in a microscopic preparation. The quantity of alcohol present in bulk kraut is normally somewhat higher than in canned kraut.

A form of manipulation that is difficult to detect is the washing of discolored kraut, such as pink kraut, a

FIGURE III

A sauerkraut vat in which juice has covered the boards. Yeast grows on the surface resulting in a secondary fermentation.

condition caused by a secondary fermentation. Such kraut may show proper color and texture, but usually has an undesirable flavor. In these cases unless the kraut is canned in brine from another tank, the canned product will be found uniformly low in total acid, volatile acid and salt.

In conclusion, it may be stated briefly that the quality of kraut bears a definite relation to its chemical composition. Defects in fermentation or in canning can often be detected by careful analyses and proper interpretation of the

results supplemented by a microscopic examination. The determinations of total acid and salt are simple procedures and the results are fairly definite. The determinations for alcohol and volatile acid are comparative and very frequently reveal defects in this food product. Microscopic examination is valuable at times as a means of detecting secondary fermentations.

The Committee on Professional Education

THE Committee on Professional Education was provided as a fifth standing committee by the Governing Council of the American Public Health Association at the Annual Meeting in Washington, 1932. Although this action was taken the actual appointment of the committee was not completed until the early part of 1933. This committee was established to replace the Committee on Training and Personnel which was a sub-committee of the Committee on Research and Standards.

The purpose of the Committee on Professional Education is to carry on studies and determine standards for the professional education of those who wish to adopt public health work as a career, and perform such other functions along this line as will raise the level of efficiency in public health administration and in the specialized phases of public health.

The By-laws provide that the committee shall consist of 10 members. The committee personnel is at the end of this report. The personnel of this committee was approved by the Executive Board at its meeting in March, 1933.

The amount of \$1,000 has been allocated by the Finance Committee for the Committee on Professional Education; \$500 of this amount is designated for travelling expenses, and the remainder for the salary of a part-time secretary.

This committee held its first meeting in New York on May 6, 1933. It was attended by all members with the exception of one who was unavoidably detained. This session of the com-

mittee was devoted entirely to a discussion of policies and objectives. A communication was sent to each member by the chairman prior to the meeting requesting that he indicate what he thought should be the activities of the committee. These communications were presented at this meeting and in a considerable measure stimulated the discussion which occurred. The primary purpose of the meeting was to determine the elements that should be considered in formulating a program. Definite progress was made in accomplishing this purpose.

As a result of this discussion it was thought desirable to consider the following problems in the initial activities of the committee.

1. Qualifications, Certification, and Licensure of Health Officers
2. Professional Qualifications of Public Health Nurses
3. Qualifications of Sanitary Engineers and Sanitary Officers (Inspectors)

It was the consensus of opinion that this work should be done under the direction of three sub-committees. The committee authorized the appointment of the following sub-committees.

Sub-committee on Qualifications, Certification, and Licensure of Health Officers

Allen W. Freeman, M.D., *Chairman*
Huntington Williams, M.D.
Thomas Parran, Jr., M.D.
C. E. Turner, Dr.P.H.
W. G. Smillie, M.D.
Stanley H. Osborn, M.D.
Clarence L. Scamman, M.D.
W. P. Shepard, M.D., *Consultant*

Sub-committee on Professional Qualifications of Public Health Nurses

Lillian Hudson, R.N., *Chairman*
 Clarence L. Scamman, M.D.
 Dorothy Carter, R.N.

Sub-committee on Qualifications of Sanitary Engineers and Sanitary Officers (Inspectors)

Ralph Tarbett, C.E., *Chairman*
 H. G. Baity, Sc.D.
 Arthur P. Miller, C.E.
 Walter S. Mangold
 J. L. Barron
 H. H. Howard, M.D., *Consultant*

The work of these sub-committees is progressing satisfactorily.

THE INSTRUCTION OF MEDICAL STUDENTS
 IN PREVENTIVE MEDICINE AND
 PUBLIC HEALTH

It was the sense of the committee that there is great importance attached to the proper instruction of medical students concerning the prevention of disease and the measures employed in public health administration. Obviously this is not being done well in medical schools at the present time. This question was discussed at some length and a sub-committee appointed consisting of Dr. W. G. Smillie, *Chairman*, Dr. W. S. Leathers and Dr. Kendall Emerson. This sub-committee was requested to prepare a memorandum with reference to this problem and present it to the Council on Medical Education, Licensure and Hospitals of the American Medical Association at its next session with a view of enlisting its interest and coöperation in stimulating changes in the medical curriculum so that students may obtain more adequate instruction in the preventive and public health aspects of medical service.

Another meeting of the Committee on Professional Education was held in New York on December 17, 1933, for the

purpose of receiving reports from the sub-committees and to determine more definitely the program for future activities.

A report was made by Dr. Freeman, *Chairman* of the Sub-committee on Qualifications, Certification, and Licensure of Health Officers, on certain principles which underlie the work of the committee, with particular reference to qualifications. After considerable discussion this report was adopted.

A report was made by Miss Hudson, *Chairman* of the Sub-committee on Professional Qualifications of Public Health Nurses, as follows:

I. Review

A. Definition of Public Health Nurse

B. Minimum Qualifications for those Appointed to Positions in Public Health Nursing

Those qualifications, adopted in 1931, will be reviewed on the basis of the findings in a recent survey made by the National Organization of Public Health Nursing. Recommendations will be made as to whether or not changes are desirable.

II. It was further agreed that the sub-committee should study the desirability of certification of public health nurses on a State or National basis.

Since the committee has met, the following has been done which may be of interest:

1. No decision has been reached as far as changing the term "Public Health Nurse" is concerned.

2. A slight change has been made in the definition of Public Health Nurse—the term "application of" having been eliminated.

This report was accepted.

Mr. Miller, in the absence of the Chairman, made a preliminary report of

the Committee on Qualifications of Sanitary Engineers and Sanitary Officers (Inspectors). He stated that much can be done to improve the training of public health engineers; that the engineering courses include too much design. The committee should also strive to elevate the standards of the sanitary officer or inspector. It is desirable to raise the qualifications for this grade of public health personnel and establish standards which will more definitely establish the status of the sanitary officer or inspector as a health worker. Mr. Miller's report was accepted.

Dr. Smillie made a report with reference to a conference with the Council on Medical Education, Licensure and Hospitals of the American Medical Association and stated that the Secretary, Dr. W. D. Cutter, agreed to have a paper on the teaching of preventive medicine on the program at the meeting in Chicago in February, 1934. The committee expressed appreciation for achieving this result.

It was the sense of the committee that a dinner session should be arranged each year during the Annual Meeting of the American Public Health

Association for the purpose of stimulating discussion concerning certain important problems in the field of professional education.

It was voted that the chairman of each of the three sub-committees be requested to bring in a report from his sub-committee concerning the minimum qualifications of health officers, public health nurses, sanitary engineers, and sanitary officers (inspectors), respectively for consideration of the main committee at its next meeting.

The discussions of the committee were stimulating and constructive and as expressed by one member, Dr. Sundwall, in a recent communication to the chairman, "the meeting was in every way worth while and real progress was made."

W. S. LEATHERS, M.D., *Chairman*
C. E. TURNER, DR.P.H., *Secretary*
LILLIAN A. HUDSON, R.N.
JOHN SUNDWALL, M.D.
HUNTINGTON WILLIAMS, M.D.
ALLEN W. FREEMAN, M.D.
THOMAS PARRAN, JR., M.D.
RALPH TARBETT, C.E.
CLARENCE L. SCAMMAN, M.D.
W. G. SMILLIE, M.D.

SAFE MILK

IT is hard to say too much on the subject of safe milk and its importance to the younger portion of our population. In the United States we are proud in believing that we come pretty near to leading the world in the precautions that we have taken and in the response of the dealers. There is abundant evidence, however, that other countries, not only in Europe but on this side of the water, are doing their best to make things as good as possible.

The January number of the *Canadian Public Health Journal* is called "Special Milk Number," and is devoted entirely to the various aspects of milk production. That country and the provinces of which it is made up, have gone through the same sort of opposition which we encountered over here, but it is most interesting to note that in 1921, the Saskatchewan Dairy Association passed resolutions favoring legislation in cities for the compulsory pasteurization of all milk and cream. Somewhat later, the National Dairy Council of Canada endorsed the principle of pasteurization, and in 1933, in Ontario, the producers and distributors adopted a province-wide law requiring pasteurization in towns and cities. In other parts of Canada, somewhat similar movements have taken place and some of them have laws requiring the counsel and advice of provincial departments of health for the approval of plans for pasteurization plants. In Saskatchewan, Manitoba and Quebec, such provisions have already been incorporated in the laws, and in others the movement is going forward. The filing of plans for such plants is closely associated with the question of licensing, which seems to be extending in our sister country very rapidly, insuring a system of adequate supervision. Canada has had some very severe lessons, notably the epidemic in Montreal in 1927, in which there were 5,002 cases, with 533 deaths. From the period 1906-1919 inclusive, but 6 epidemics were recorded, while in a similar period, 1920-1933, there were 42. While increase in population may have had something to do with this increase in epidemics, the authorities believe that the difference shows clearly the

active participation of health authorities, local and provincial, in the care of milk and the investigation of diseases. The following epidemics have been recorded:

	<i>Epidemics</i>	<i>Cases</i>	<i>Deaths</i>
Typhoid	35	6,514	674
Paratyphoid	3	522	3
Scarlet	7	192	0
Septic Sore Throat	3	584	4
	<hr/> 48	<hr/> 7,812	<hr/> 681

Pasteurization is not as widespread in Canada as might be desired. According to available statistics, only 25 municipalities require that all milk sold be pasteurized. Altogether, a population of 3,067,362 is served with pasteurized milk to a greater or less extent. Only 5 of these report that 100 per cent of their milk is pasteurized, 12 of them reporting that 100 per cent of the cattle furnishing the milk is tuberculin tested. As a rule, the cities that endorse pasteurization most strictly are those in which tuberculin testing is best carried out, but there are some notable exceptions. Windsor and St. Catharines, for example, apparently depend almost entirely on pasteurization, the tuberculin testing running only 5 per cent for the former city, and 8 per cent for the latter.

The review of the situation in Canada includes a short but excellent study of the nutritional value of pasteurized milk, ending with the conclusion that observations on large groups of children have shown that growth is as satisfactory with pasteurized milk as with raw, and pointing out that calcium is the only valuable dietary constituent which is affected, and ending with the advice that some source of vitamin C be included in the diet.

This Special Milk Number is full of interest and can be recommended for study by all health officers, producers and distributors.

ORAL HYGIENE

ONE has only to scan the literature casually to recognize the prominent place in prevention of disease that oral hygiene has come to occupy. When one tries to write on the subject—except for fundamental principles which are generally accepted—he finds himself lost in a maze of contradictions and uncertainties; yet we feel that all interested in this phase of preventive medicine should attempt to keep up with the advances which are being made.

For some years attention has been largely focused on the part played by vitamins in the development of the teeth, and to some extent even in the arrest of caries. All agree that proper nutrition plays a large part in the development of the teeth, but it is equally sure that proper development may be a very different thing from proper maintenance. It has not yet been shown whether these different requirements are quantitative or qualitative.¹

Many studies have been made on the composition of teeth, and Hoppe-Seyler as early as 1881, pointed out that the dentine of the tooth might be called bone in its purest form. Many studies have been made also on mineral metabolism, especially calcium and phosphorus. Some authentic work has shown that during the last month of pregnancy there is a loss of calcium amounting in some cases to 0.5 gram per day. Long before these observations, the old saying, "A tooth for every child," was common. In some of the lower animals, when the

mother receives a poor diet during pregnancy and lactation, the teeth of the offspring show less calcification. Sherman has shown that in American diets, if there is a deficiency, it is likely to be in respect to calcium. On such findings is based the advice, so widely given, to use milk, since the average calcium requirement of children is about 1 gram per day, and milk is our best source for this element. Whether such teeth are more liable to caries or not is questionable. The work of Mrs. Mellanby, who lays so much stress on vitamin D and also on vitamin A, is well known. Against this, studies at Yale have led to the conclusion that there is no constant parallelism between rickets and subsequent susceptibility to caries. In cases of severe rickets in infancy, a greater incidence of caries is found, while in respect to the permanent teeth in 7 year old children, no significant difference in the incidence of caries in the hypoplastic and non-hypoplastic groups was observed.

Perhaps the animals that we have used experimentally are not the best suited for such work, as is suggested in the article by Cowgill.¹ Mrs. Mellanby was not able to produce caries in puppies regardless of their dental structure. Bunting, at Michigan, has found the same difficulty and has suggested that the conical shape of the dog's teeth plays a protective rôle. Many dentists hold that the relative resistance of the canines in man is due also to their shape. Bunting goes back to the idea, held for so many years and still believed in by many dentists, that the carbohydrate diet of man is responsible to a great extent for caries, and gives records of groups of children fed under his direction which are hard to explain otherwise.

Certain observers claim that the intake of extremely large amounts of vitamin D results in the development of caries. Their experiments were done on animals fed a rachitogenic diet low in phosphorus, and the experiments of other observers contradict these results. Mrs. Mellanby feels sure that vitamin A has a marked effect in preserving the health of the gingival tissues and that by proper feeding, caries may be arrested and to a certain extent healed, though she admits that the mechanical movements of the mouth have something to do with the results.

On the other hand, Bloch believed that vitamin A is in no way related to the development of caries. It seems to have been definitely proved that in some species, vitamin C has something to do with the proper development of teeth. A shortage of this factor is evidenced by a derangement of the odontoblastic cells and failure of the newly formed dentine matrix to harden. Cowgill points out that the number of variables operating in nutritional investigations is very great and the planning of a nutritional experiment along these lines is difficult. Consequently, it is not surprising that no one is able to make precise statements concerning the relation of the dietary factors involved in the maintenance of healthy teeth. He suggests that experiments on monkeys and apes might give results which are more reliable, and calls attention to the fact that many laboratories now are using such animals quite extensively so that it may be easily possible to extend the observations along the lines of dental health.

While it is believed that everyone who has studied the question recognizes the many conflicts of opinion as well as experimental evidence, there are certain fundamentals about which we can speak surely. We should recognize and give credit to the work of the dentists in calling the attention of the public to many of these matters, especially the necessity of correcting errors of occlusion, irregularities of teeth, and maintenance of cleanliness. As the dentist sees the majority of children early, often before they are carried to a physician, he is in a position to detect the

early signs of beginning systemic disease. Owing to this, there should be a much closer relation between physicians and dentists than now generally exists. For a long time dentistry was largely occupied in the mechanical factors of prosthesis. Without belittling the necessity of this work, it must be pointed out that it is often only a small part of the problem, and is often done more for esthetic purposes than for the prevention of systemic disease. It is interesting to note that this factor was operative as far back as the time of Solomon who complimented the Queen of Sheba as follows: "Thy teeth are like a flock of sheep that are even shorn, which come up from the washing." In the doggerel of today, the same idea has been expressed, "And teeth so white, you almost wish your ear she'd bite."

Preventive measures would call for a broadening of the scope of dental reparative work, such as is being carried out at present in some of our cities. At once we come in touch with a great social and economic question; namely, public health service.² We may then say positively that oral hygiene in general has a place, and a most important place, in the scheme of preventive medicine, and is worthy of the attention not only of physicians and dentists, but of health officers.

LETTER TO THE EDITOR

TO THE EDITOR:

PRECISION in the use of words, numbers or symbols is a characteristic of the exact sciences. The word "oxygen" means the same thing to scientists everywhere; the number "one" has a constant meaning for all mathematicians; and the symbol " H_2O " is interpreted as water uniformly and definitely by chemists throughout the world.

When we consider the so-called "social sciences" we find no such universal dictionary of definitions. Words do not have a common connotation. This leads to confusion, prolific explanations and oftentimes to misunderstandings.

In the field of public health, outside of the use of legal, medical, and engineering terms, confusion is worse confounded. The legal profession can turn to *Black's Law Dictionary*; the medical profession, to *Dorland's* and *Stedman's*

Medical Dictionaries; and the engineers, to the *Engineering Index*. If public health is to attain a position as a science there is need for a "Dictionary of Public Health."

Abundant illustrations which serve to point this need can be brought forward. It is a commonplace in current public health discussion to find "doctor" used interchangeably with "physician." Custom, traceable to earlier conditions in society when the professions were limited, sanctioned "Reverend" as the hall-mark in the ministry; "professor," in education; "doctor," in medicine. With the rapid diffusion of higher education, particularly in the United States, there has come an immense proliferation of degrees until today the earlier marks of the professions have become so jumbled as to be well-nigh meaningless.

As a matter of fact, the word "doctor" nowhere appears in a medical

dictionary—but there does appear the abbreviation “M.D.,” or doctor of medicine.

Again, in the current issue of *Public Health Reports*¹ in which appears a directory of whole-time county health officers for 1933, such officers are designated by law as follows:

Alabama—County Health Officer; Arizona — Director; Connecticut — Superintendent of Health; Georgia—Commissioner of Health; Massachusetts —Director of Public Health; Medical Director; and County Health Officer; Michigan—District Health Officer; Pennsylvania—County Medical Director; and Virginia—just plain health officer. Is it any wonder the poor layman stumbles and is confused when he seeks for the term with which to describe the administrative official charged with the public responsibility of protecting the health of the community?

One further example will suffice. In the recent issue of the volume *Community Health Organization*,² the current hesitation in the selection of the term to describe public health activities carried on outside of the official field, one will find the following words used interchangeably within the space of 10 pages — private — voluntary — unofficial—non-official.

That there is need for exactness of expression has been demonstrated from time to time. The *American Journal of*

Public Health has listed occasionally in its pages words and phrases employed in public health work, with their definitions. Since public health is a composite discipline drawing its materials from medicine, engineering, law, statistics, nursing, education, social science, and administration, it would seem that some effort should be made to compile a dictionary for the benefit of the workers in the public health field.

If mass education of the public in health matters is to proceed apace, certainly the public health workers themselves should be able to employ their tools with a minimum of hesitation and obfuscation. It is true, such a task would be time-consuming, expensive, and difficult, but until it has been undertaken public health will continue its stumbling and halting progress toward its goal as a science.

Dr. Oliver Wendell Holmes was not far wrong when he said “Science is the topography of ignorance,” and equally well could have said there is need of topographers in science. Particularly is this true in the area of public health.

LETTER FROM GREAT BRITAIN

THE OVERSHADOWING SLUM

At the end of 1933, as for a considerable time before, in public health circles here the main pre-occupation of the authorities and their officers appeared to be housing. For months the Minister of Health had been engaged in visiting various parts of the country, seeing for himself how matters stood,

and urging, encouraging, and threatening the persons responsible in areas in which arrangements for assisting forward his 5-year plan of slum clearance were hanging fire or had not been put in hand. Speaking generally, in most districts it is almost true to say that apart from housing activities, and largely because of them, little more than

the ordinary routine work received attention during the year.

Fortunately, there has been no marked prevalence of any particular disease for some time, and, so far as death rates show, the infant welfare and tuberculosis schemes are functioning satisfactorily. Exactly the amount of faith that should be reposed in death rates as a guide is always difficult to decide. Even in this matter of slum clearance, death and to an extent also disease rates frequently fail to lend support to those who are pressing for removal, proving infinitely more useful to those who are backing the owners of the slums and objecting to schemes of clearance.

So again frequently is it in the case of persons transferred from slums and placed in what appear to be improved surroundings. In this connection I have referred already, I think, to the investigations of Dr. G. C. M. M'Gonigle, Medical Officer of Health of Stockton-on-Tees, who found that both the mortality and morbidity rates noted among re-housed individuals were higher than in those who remained in the slum area.

HOUSING, MORBIDITY AND MORTALITY

Dr. M'Gonigle's explanation of this difference was that the persons in the newer houses, having to pay more in rent had less to spend on food, and had less resistance therefore to offer to disease. This doctrine was one very readily accepted by quite a number of people, particularly those who have been responsible for the raising of the barriers to progress in slum clearance.

The determination not to permit these barriers to remain, or such considerations as were put forward by Dr. M'Gonigle to strengthen them, culminated in the initiation of the drive which has been one of the outstanding features of 1933.

Who exactly has been responsible for

it is quite difficult to make out. Definitely there must have been some special impulse, and there is strong reason to believe that it came from the Royal Family. That the King and Queen are and have been gravely concerned is, of course, well known, and the Prince of Wales has spoken very freely on the subject on numberless occasions and in a variety of places.

Sir Hilton Young, who himself carries the fiery torch, speaking at the dinner of the Society of Medical Officers of Health in November, claimed that the medical officers of health were the spear-head of the attack. It is undoubtedly the case that these officers have very heavy responsibilities in this matter. These they have never neglected. Nor have they neglected to condemn the slum, to deplore the conditions under which so many of the people for and among whom they worked were compelled to exist, and to urge that action should be taken.

Practically there is no medical officer of health who has not directed attention, not once but many times, to the existence of slum conditions, recorded his opinion that these conditions were inimical to health, and urged that they should be dealt with. In doing so he has defied statistics, and on such occasions as the call for action has been heard and procedure for securing clearance has been taken, has had to suffer for his temerity at the hands of counsel and witnesses engaged by those opposed to action.

UNEMPLOYMENT AND THE PUBLIC HEALTH

Another connection in which death and disease rates and such-like statistical manifestations appear to certain people to fail to provide evidence supporting that gathered by the senses affects infants. Here and there, in several places, there are medical officers of health and others who—while prepared

to agree that the infantile mortality rate, not only for the country as a whole but in the bulk of areas, keeps low and that it is permissible to accept this as indicating that unemployment is not exerting an influence inimical to the young—are not completely convinced that all is so well as we are asked to believe.

There are quite a number of areas in which the rates are tending to rise; in which wasting and marasmic conditions and such things as enteritis are more prominently present than has been the case for some years. There are, too, many reports from health visitors and voluntary workers at welfare clinics and in the homes of the people that very many more families are showing signs of strain than was formerly the case. Adult members of families, it is claimed, have been sacrificing themselves for a long time in order that the younger ones shall not suffer, and are now beginning to show signs.

In matters of this sort it is easy, of course, to attach exaggerated importance to cases that actually are isolated. It is a fact, however, that in most health departments the health workers who are out and about among the people have reports of this kind to make, and, as a result, that glow of satisfaction that the growing feeling of optimism should bring is less rosy than perhaps it should be.

THE EXPECTED MEASLES EPIDEMIC IN LONDON

By many of our forecasters it is promised that 1934 will prove to be a measles year. In the metropolis, at any rate, it is regarded as a certainty that it will reach epidemic proportions, and health officers and authorities are urged to make preparations accordingly. Largely these have reference to routine matters involving closer and more frequent supervision of school children, at

welfare centers and in the homes of the people.

Comparatively little in the shape of immunizing work has been done as yet in this country in respect of measles. It is possible, however, that if opportunity presents, much more may be done in London during the epidemic that is forecast for 1934–1935, a considerable amount of experience having been obtained in the last epidemic of 1931–1932, with results sufficiently encouraging to justify work on a wider scale.

In a report of the Medical Officer of Health of the London County Council dealing with the outbreak of 1931–1932, it is shown that special attention was devoted to the question of the employment of serum, more particularly human adult serum in the control of measles.

Adult Serum in Measles—The contribution on this subject to the report by Dr. Gunn, Deputy Medical Superintendent of the North Eastern Hospital of the London County Council, is of real value, as is also a statistical paper on the same question by W. T. Russell of the London School of Hygiene and Tropical Medicine.

The total number of observations recorded was 2,362. The adult serum series numbered 1,475, while there were 680 injections of convalescent serum, the uninjected contacts numbering 207. These numbers are, rightly, regarded as rather small when it comes to drawing conclusions on some of the finer points. Certain general conclusions, however, are sufficiently well based and may safely be drawn. Among these may be noted that as to the utility of adult serum in relation to prophylaxis. This provides support for the view that it is an agent of real value. The statement made, indeed, is to the effect that in its protective and attenuating action it is only slightly inferior to convalescent serum. Having regard to the fact that

it is so very much more readily obtained than the convalescent serum, and its collection, storage, etc., present comparatively little difficulty, it is likely to occupy a prominent place in any future policy of measles control. The report gives very detailed and clear information on these matters likely to prove useful to authorities and officers

desirous of including adult serum as part of their armamentarium against a disease which, though the public refuse to appreciate it, constitutes one of the most serious and difficult of the epidemiological problems with which preventive medicine is faced.

reau of Adult Welfare

MRS. FRAAS APPOINTED TO NEW
POSITION

Mrs. Alma W. Fraas, Secretary of the
Committee on Administrative Practice,
has left the Association to become Sec-
retary to the Commissioner of Health of
New York City, Dr. John L. Rice.
She was formerly a member of the Re-
search Division of the American Child
Health Association and for the past
several years has been Secretary of the
Committee on Administrative Practice.

PUBLIC HEALTH ADMINISTRATION

THE FAMILY PHYSICIAN AND DENTIST IN PREVENTIVE MEDICINE

GEORGE B. DARLING, JR., DR.P.H.

W. K. Kellogg Foundation, Battle Creek, Mich.

INCLUDED in the summary of findings and conclusions of the committee which studied city health organizations for the White House Conference on Child Health and Protection, there appeared the following:

Some activities now included in the program of most health departments can be transferred gradually to the general practitioner of medicine. In the interest of child health, in so far as practical, the family physician should become a practitioner of preventive as well as curative medicine. He should take an interest in seeing that his clients are protected against smallpox, typhoid fever, and diphtheria, and that adequate periodic physical examinations are made. The public health service should stimulate interest in extending postgraduate instruction to the general practitioner of medicine to interest him in this type of service, and also to establish reasonably uniform methods of procedure.

There is a growing tendency to improve the coöperative relationship between local health organizations, both official and voluntary, and the medical and dental professions. In the expansion of such services, it should be understood that there is no place in such plans of professional participation in health work for the elimination or even the curtailment of the work of the official local health department. On the contrary, the first essential of such an enterprise should be the establishment of a whole-time, properly personneled and reasonably financed, local health department. Such a recommendation was unanimously approved by the delegates to the last annual meeting of the

Michigan State Medical Society and this state organization is now engaged in a plan for extending such coöperative services to every county in Michigan.

Noteworthy progress has been made during the past 20 years in reducing death rates and in minimizing the prevalence of such communicable diseases as typhoid fever, smallpox, and diphtheria. Nineteen hundred and thirty-three will be remembered throughout the nation as a year of low death rates, one with new, low, all-time records for many infectious diseases. Apparently we have been carried forward by the momentum of previous years, as a direct result of the seeds of health education which were so effectively sown during the more prosperous times. The public mind has been aroused to the necessity of community effort in the furtherance of public health services. While there may be momentary lapses in the health programs and temporary curtailments of adequate support for health problems, there can never occur a reversion to the high mortality of 20 years ago. Our people are demanding protection for themselves and for their children. The local health machinery must be maintained in good working order. The health officers must use their ingenuity in finding the means with which to carry them through the period of stress and strain.

In general the medical aspects of the local health program can be provided

in either one of two ways: first, by the employment of physicians and dentists on a salary basis; or second, by bringing into active coöperation the existing professional resources of the local community so that the doctors and dentists will practise preventive medicine along with curative medicine in their own offices. The fulfillment of this last mentioned program requires the hearty coöperation of the health officer who must act as a stimulating agent in forcibly bringing to the attention of the public the need of such preventive services and in coördinating the activities of the various professional groups.

The progress in this direction is well illustrated in the annual report of the Barry County Health Department just released by the Health Officer, Dr. M. R. Kinde. Barry is a typical rural county located in the southwestern part of the State of Michigan. The only city is Hastings with a population of 5,227. There are four incorporated villages. The county has a population of 20,928, of whom 96 per cent are native white. The county contains 560 square miles and has an efficient County Health Department consisting, in addition to the Health Officer, of a sanitary engineer, a public health nurse, and a clerk. The W. K. Kellogg Foundation has also assigned to this county 4 public health nurses all of whom are qualified graduate teachers. Certain additional services are from time to time provided by the Foundation.

In this rural area the physicians and dentists have organized themselves so that they have become an important part of the health machinery of the community. The Health Department serves as a coördinating body; the Health Officer himself serves as secretary of the County Medical Society and acts in an administrative capacity in formulating the services and in organizing the work which is carried on

by the physicians and dentists so far as possible in their own offices.

At the beginning of the year 1933 it was determined that every school child in both the rural and urban schools should receive a health examination at the hands of the practising physicians working under a plan controlled jointly by their local medical society and the Health Department. Each physician has taken his turn in giving the screening examination to the children at school. The dentists have organized a similar program. Following such service, the more thorough and detailed examinations, and the corrective services are provided by the professional men in their own offices where not only the school children, but the children of preschool age receive their diphtheria protection and are vaccinated for smallpox. An intensive educational program to encourage the coöperation of the parents has been sponsored by the County Commissioner of Education and promulgated through the medium of the school teachers and with the coöperation of the public health and teacher nurses.

The principle of the entire program is to bring the child in closer relationship with the family physician. The Health Officer states that it has long been realized that preventive and curative medicine cannot be separated and both are functions of the family physician.

An additional essential of such a program of professional coöperation is the necessity to prepare the profession, first, with respect to the group plan which should be under the control or supervision of the local medical society and health department, and second, with regard to the technical procedures to be followed. The physician in private practice should be willing to subordinate his views and plans to those sponsored by the organized profession. Failure to do so would result in mis-

interpretation on the part of the public. In the carrying out of diphtheria protection services each physician must be conversant with the accepted practices; he must know whether toxin-antitoxin or toxoid is to be used; he must have a knowledge of the reactions which may be expected in children at various ages; he must know the length of time for which protection is usually given; and he must be prepared with answers for the numerous inquiries which will occur to the public mind.

To provide postgraduate work for the physicians and dentists of Barry County, the W. K. Kellogg Foundation established a series of postgraduate fellowships not only for Barry County but for the neighboring counties of Allegan and Eaton. Of 72 physicians

resident in these rural areas, 56 have already completed their first course in postgraduate training, and of 34 dentists, 28 have had the advantage of similar training. These fellowships provided for a 2-week intensive course and most of the physicians and dentists received this training at recognized professional centers in Chicago. In addition, men of professional ability have presented special subjects in the field of preventive medicine to the physicians at their own county meetings.

Experience thus far indicates that it is perfectly practical under rural conditions to carry on a coöperative health program where a well organized local health department works harmoniously with the local dentists and physicians.

Commonwealth Fund, New York City—For more than 10 years the Fund has entered into partnership with local health and hospital organizations with the view of extending the responsibility for maintaining new services or standards of health work, in so far as possible, through local financial support. The stressing of local participation in financing health and welfare projects is one of the basic principles on which the Fund has constructed its activities.

During the fiscal year ended September 30, 1933, the Commonwealth Fund expended more than \$1,600,000, nearly half of which (46 per cent) went into the field of health. The program has involved rural health service, rural hospital service, medical education, and medical research. It has now been 5 years since the Fund withdrew its support for the health demonstration in Fargo, N. D., and the community has since maintained its own public health program. The health department has been accepted as one of the essential normal divisions of the local government. The character of performance

has not suffered during the past 5 years as evidenced by the fact that in 1932 Fargo scored 845 points on the *Appraisal Form*. Like most American communities, economies have of necessity been made in the health service but last summer when further cuts were considered a group of citizens complained so rigorously that the city commission refused to make any further cuts in the health department appropriations. In addition to the Health Officer, the staff consists of 6 nurses and a supervisor, a milk inspector, a half-time dentist and 2 clerks. The only loss suffered due to the depression has been a second inspector and a part-time medical assistant.

During the fiscal year the Fund has continued to support health activities in Massachusetts, Mississippi, and Tennessee. In spite of the loss of nearly 50 per cent in its appropriations, the Tennessee State Health Department has maintained its excellent standards, and in 4 counties in Tennessee and Mississippi, where the Fund has aided in the maintenance of health service, the

appropriations have been definitely increased. In Lauderdale and Pike Counties, Miss., the health departments are employing private physicians as clinicians in various fields of public health service. This is considered an alternative to adding medical assistants to the health department staff, which is the preferred plan in Tennessee. In all of the 6 local coöperative enterprises in 3 states, the application of the *Appraisal Form* as a measuring stick indicates a higher score for 1932 than that attained in the preceding years.

The Commonwealth Fund has continued its support of the activities of the Committee on Administrative Practice of the American Public Health Association, and has published for the committee a review of rural public health service by Dr. Allen W. Freeman.—*Ann. Rep., Commonwealth Fund, 1933.*

Washington, D. C.—The annual report for the year ending June 30, 1933, is published with the general report of the government of the District of Columbia and contains the vital statistics for the calendar year 1932, when the death rate in this city of 493,000 was 16.12, slightly higher than that for each of the three preceding years. During the calendar year 1932, there were reported 401 cases of diphtheria, of which 16 resulted in death; 814 cases of scarlet fever with 13 deaths. Diphtheria protection service has been provided through the schools and through the child hygiene centers. The health officer is not satisfied with the extent of this immunization service, there having been 7,642 children given the Schick test during the fiscal year, of which number 4,682 gave a positive reaction and to 4,510 of whom toxoid was administered.

Typhoid fever was the cause of 6 deaths among 67 reported cases. This

may be compared with 64 cases and 19 deaths for the preceding year. Of the 67 cases reported in 1932, a history of outside infection was found in 23 instances. Epidemiological studies disclosed evidence that indicates 15 per cent of the typhoid cases were due to eating raw oysters, 13 per cent to the consumption of ice cream, and 61 per cent to raw vegetables. The infant mortality rate in 1932 was 73.6 per 1,000 births.—*Rep. Government of the District of Columbia, year ended June 30, 1933.*

Maryland—The death rate from all causes in 1932 was 12.6 per 1,000 population; the infant mortality rate 69.5 and the maternal rate 5.0 per 1,000 live births. By the end of the year 22 of the 23 counties in Maryland representing 98 per cent of the total population outside of the City of Baltimore, were organized on a full-time basis. Beginning with Allegany County in 1922 the whole-time local rural health services have gradually been expanded until now virtually the entire state has been covered. Each full-time county health officer also serves as a deputy state health officer.

For the entire state there were reported 695 cases of typhoid fever, with a death rate of 3.1. Of this number 593 cases were reported from the counties; 46 ended fatally. For Baltimore there were reported 102 cases with 6 deaths. Diphtheria claimed the same total number of victims. Of the 52 deaths, 17 occurred in Baltimore and 27 in the counties. The diphtheria prevention activities have been concentrated on the protection of younger children, 14,050 of whom were immunized against the disease during the year. There were reported 49 cases of Undulant Fever and 26 cases of Tularemia.—*Ann. Rep. for 1932, State Department of Health.*

LABORATORY

THE EFFECT OF AGE, DILUTION, AND DOSAGE UPON THE IMMUNIZING VALUE OF DIPHTHERIA TOXOID

WILLIAM LEVIN, DR.P.H., F.A.P.H.A., AND HELEN A. CARY, M.D., F.A.P.H.A.
*Director, Hygienic Laboratory, State Board of Health, Portland, Ore.; and
Medical Director, City Schools, Portland, Ore.*

IN a previous paper¹ we had reported finding considerable variation in the antigenic value of commercial diphtheria toxoids as determined by the Ramon flocculation test, by guinea pig protection tests, and by human experimentation. Greengard² found a variability in antigenic potency of several batches of commercial diphtheria toxoids as determined by immunization of infants. Povitzky,³ in examining toxoids from different manufacturers by means of the flocculation test, found a wide variation in their antigenic values. Of the five toxoids tested by us, three had been diluted, two in a ratio of 1 to 1, and one in a ratio of 1 to 3. The highest immunity had been obtained with an undiluted toxoid. It seemed probable that dilution was one of the factors affecting the potency of toxoid. Whether or not the age of the toxoid had any appreciable effect on its antigenic value was deemed worthy of consideration and study, particularly since

federal regulations allow an expiration time of 18 months on this product. The question of dosage was also considered of sufficient importance for further investigation. To determine, therefore, the effect of dilution, age, and dosage upon the immunization value of diphtheria toxoid, a series of tests was carried out, the results of which are presented in this paper.

A preliminary Schick test was given to 1,016 children between the ages of 1 and 15 years, 84 per cent of whom were in the 4 to 10 year age group. None of these children, so far as could be determined, had had diphtheria or had been immunized against it. The results are given in Table I.

Through the kindness of the Cutter Laboratory a supply of diphtheria toxoid and toxin was made available to us. Toxoid lot No. 9163 was prepared in April, 1932. This toxoid was divided into two portions early in June, 1932. One portion was left undiluted

TABLE I
RESULTS OF PRELIMINARY SCHICK TEST

Age Group	Total No. Tested	Schick Positive	Per Cent Non-Immune
1-3	55	51	92.7
4-5	124	111	89.5
6-10	726	626	86.2
11-15	111	86	77.5
Total	1,016	874	86.0

TABLE II
FLOCCULATION VALUES OF TOXOID LOT NO. 9163

<i>Toxoid</i>	<i>Date Tested</i> 1932	<i>Lf</i>	<i>Units per c.c.</i>
Undiluted	April 18	0.086	11.63
Undiluted	May 5	0.076	13.16
Undiluted	Nov. 22	0.076	13.16
Old Diluted	Nov. 22	0.152	6.58
Freshly Diluted	Nov. 22	0.138	7.25

and the other was diluted with an equal amount of salt solution and preservative. This diluted toxoid we shall speak of as the "old diluted toxoid." Another portion, the "freshly diluted toxoid," was later prepared from the original lot of toxoid, a dilution of 1 to 1 being made about a week prior to the first injection. Immunization of the children was begun in the latter part of November, 1932, and was carried on through February, 1933. Schick positive reactors only were given the toxoid immunization. Those that gave a combined (protein) reaction were excluded.

The flocculation values of the different toxoid portions were determined by Dr. Harry E. Foster of the Cutter Laboratory. The Lf value of the stock undiluted toxoid was 0.086 in April, 1932. Tests on all portions were carried out in November, 1932, 7 months after the original lot of toxoid had been made, and immediately after the freshly diluted portion had been prepared. His figures are given in Table II.

In commenting upon these values Dr. Foster states:

Judging from the figures alone there would appear to be a discrepancy in these tests, since theoretically the specially (freshly) diluted material could not have a value better than 0.152. Practically, however, there is sometimes difficulty in telling which of the two adjacent tubes first shows flocculation and it is quite possible that in the test on undiluted toxoid the tube containing 0.076 and that containing 0.068 came down approximately together.

Anderson, Leonard, and Holm⁴ are of the opinion that the flocculation reaction

is not always specific, and, therefore, is not always a true measure of the antigenic value. They state further that the flocculation time is not always a true measure of avidity, as determined by flocculation. In our previously reported work¹ we showed that the guinea pig protection test gave a truer index of potency than the flocculation test.

Guinea pig protection tests were carried out on the undiluted and the old diluted portions of the toxoid. Unfortunately, guinea pigs of the size used in the protection test, 280 to 300 gm., were unavailable to include tests on the freshly diluted toxoid. Five guinea pigs were injected subcutaneously with 1 c.c. of the old diluted toxoid; 5 with 0.5 c.c. of undiluted toxoid; and 5 with 1 c.c. of undiluted toxoid. Four of the animals were subsequently lost because of death from septicemia. Six weeks later the survivors were given varying amounts of diphtheria toxin. The results are shown in Table III.

A study of Table III indicates that the undiluted toxoid gave greater protection than the equivalent amount of diluted old toxoid. Because of the few animals used no conclusions could be drawn as to the superiority of the 1 c.c. dose over the 0.5 c.c. dose of undiluted toxoid.

A total of 766 children were given the toxoid. They were divided into four groups. One group was given undiluted toxoid in two 0.5 c.c. doses at an interval of 3 weeks. A second group was given three 0.5 c.c. doses undiluted toxoid at

TABLE III

GUINEA PIG PROTECTION TESTS WITH OLD DILUTED AND UNDILUTED TOXOID, No. 9163

Diphtheria Toxin in M.L.D. Doses

Toxoid No. 9163	Size Dose	Floc. Units Injected	5		10		20		40	
			Guinea Pigs Inj.	Surv.	Guinea Pigs Inj.	Surv.	Guinea Pigs Inj.	Surv.	Guinea Pigs Inj.	Surv.
Old Diluted	1 c.c.	6.6	2	1	2	0
Undiluted	0.5 c.c.	6.6	1	1	1	1	1	0
Undiluted	1 c.c.	13.2	1	1	1	1	1	0	1	1

intervals of 1 week. A third group was given two 1 c.c. doses of the old diluted toxoid at an interval of 3 weeks. The fourth group was given two 1 c.c. doses of the freshly prepared diluted toxoid at an interval of 3 weeks. All groups were re-Schicked 3 months after the final toxoid injection.

Of the 766 children given the toxoid, 620, or 81 per cent completed the various courses of injections and were available for the final Schick test. It is rather a coincidence that exactly the same percentage of children available for the final Schick test was obtained in our previously reported work on toxoid immunization.

The diluted toxoid apparently loses potency upon aging since the freshly diluted toxoid gave over 5 per cent more immunes than the old diluted toxoid. It is probable that had the immunization tests been carried out at the expiration date of the toxoid—a good year later—a more striking difference between the old and fresh toxoids might have been obtained. The results obtained with the guinea pig protection tests also strengthen our belief that diluted toxoid loses potency upon aging,

and that if diluted toxoid is to be used at all, a shorter expiration time should be required.

The question of dosage has been given considerable study and investigation by many workers. In our previously reported work we obtained from 82 to 100 per cent immunes when two doses of 1 c.c. each were given at a 3-week interval. The highest percentage immunes obtained in our present series, 98 per cent, resulted from three 0.5 c.c. doses given at weekly intervals. Advocates of the alum precipitated toxoid claim a 95 or higher percentage immunes with a single dose. It is a well known fact that repeated injections of an antigen increases the immune bodies in the reacting animal or human. Such increases are usually not proportional to the amount of antigen injected. There is evidence that a definite quantity of toxoid given in divided doses will give more protection than if given in a single dose. Park and Schroder⁵ showed that a single dose of $\frac{1}{4}$ c.c. toxoid will protect a guinea pig against 10 m.l.d. toxin; whereas, if given in two doses of $\frac{1}{8}$ c.c. at an interval of 1 week, 20 m.l.d. will be overcome; and if given in three doses

TABLE IV

IMMUNIZING VALUE OF OLD DILUTED, FRESHLY DILUTED, AND UNDILUTED DIPHTHERIA TOXOID

Toxoid No. 9163	Size Dose	No. Doses	Total Floc. Units	Interval between Doses	No. of Children Injected	No. of Children Negative on Re-Schick	Per cent Children Immunized
Old Diluted	1 c.c.	2	13.2	3 weeks	153	135	88.2
Freshly Diluted	1 c.c.	2	14.5	3 weeks	168	157	93.5
Undiluted	0.5 c.c.	2	13.2	3 weeks	161	145	90.1
Undiluted	0.5 c.c.	3	19.7	1 week	138	135	97.8

of 1/16 c.c. with intervals of 1 week, 40 m.l.d. will be overcome. Povitzky³ also demonstrated that the degree of immunity is enhanced if a stated quantity of toxoid is given in divided rather than in a single dose. For these reasons we are of the opinion that the number of doses rather than the number of flocculation units influences the percentage of immunes obtained with any given toxoid.

A small number of children were re-Schicked who, through illness or for other reasons, had been unable to complete the full course of injections. Twenty-two children were given one injection of the old diluted toxoid; 7, or 31 per cent, were negative on the re-Schick. Six children given one injection of the freshly diluted toxoid were still positive on the re-Schick. Of 5 children given only one injection of undiluted toxoid, 3, or 60 per cent, became Schick negative. Of 10 children given two injections of the undiluted toxoid at a weekly interval, 9, or 90 per cent, were negative on the re-Schick.

The inference of Massey⁶ that rural children do not react to the Ramon toxoid to the same degree of immunization as do urban children was not corroborated by our findings. Of the 620 children given the toxoid injections 180 were from distinctly rural communities. The results obtained on these rural children are indicated in Table V.

Ninety per cent of the rural children were immunized with the toxoid, whereas, 93 per cent of the urban children were so immunized. These figures certainly confirm Dr. Park's findings of 90 to 98 per cent immunes in young children who receive two doses of Ramon toxoid. The low percentage of immunes obtained by Massey—61 per cent—might probably be explained by the use of a toxoid low in immunizing value. Occasionally even the Schick toxin may not be as strong as or even stronger than the label indicates. Several years ago, one of us (W.L.) on checking a commercial diphtheria toxin used for the Schick test found it to be exactly four times as strong as the label indicated.

CONCLUSIONS

Diphtheria toxoid may be expected to give a high percentage of immunes if it be of high antigenic value as determined by the guinea pig protection test. Of 620 Schick positive children given toxoid, 572, or 92.2 per cent, were found to be Schick negative 3 months after the last injection. Rural children reacted equally well as the urban children. Toxoid which has been diluted loses some of its potency upon aging, and the expiration time of 18 months allowed by the federal government is too long. Undiluted is preferable to diluted toxoid. Three 0.5 c.c. injections of un-

TABLE V

INCIDENCE OF DIPHTHERIA SUSCEPTIBLES AMONG RURAL CHILDREN AND PERCENTAGE IMMUNIZED BY RAMON TOXOID

<i>Preliminary Schick Test</i>				<i>Immunization with Toxoid No. 9163</i>			
<i>Age Group</i>	<i>No. Tested</i>	<i>Schick Positive</i>	<i>Per cent Non-immune</i>	<i>Toxoid</i>	<i>No. Inj.</i>	<i>No. Negative on Re-Schick</i>	<i>Per cent Immunized</i>
4-5	16	15	93.7	Old Diluted	46	40	87
6-10	202	163	80.7	Freshly Diluted	43	40	93
11-15	80	56	70.0	Undiluted (2 doses)	58	50	86
				Undiluted (3 doses)	33	32	97
Total	298	234	80.0	Total	180	162	90

diluted toxoid at weekly intervals gave 98 per cent immunes. For the physician who sees the child in his office this three-dose course should be the one of choice if the Ramon toxoid is to be used. Practically no reactions are obtained with this size dose. On the other hand, where the health officer and physician have to give the injections in the field, two doses of 0.5 c.c. and 1.0 c.c. undiluted toxoid or two doses of 1 c.c. of freshly diluted (1 to 1) toxoid, given at a 3-week interval may be recommended. With a potent toxoid, either with the two or three dose injection, at least 90

per cent immunes may confidently be expected.

RESOLUTION ADOPTED BY THE RESEARCH COMMITTEE OF THE INTERNATIONAL ASSOCIATION OF ICE CREAM MANUFACTURERS, AT ITS MEETING IN CHICAGO ON SEPTEMBER 18, 1933

WHILE this committee fully realizes the importance of research in the matter of determining the bacterial count in dairy products, it deplores the fact that at times the results of such research are made standard practice, thereby resulting in different agencies using different methods. This committee wishes to go on record as strongly recommending that all agencies having to do with determining the bacteria count in dairy products adhere to the published American Public Health Association methods. The committee feels certain that the proper committee of the American Public Health Association will at all times be glad to entertain the results of research pointing toward the need of a change in their published methods.

Dr. Robert S. Breed, Chairman, Committee on Standard Methods for the Examination of Dairy Products, comments, in a letter to the Executive Secretary of the A.P.H.A., as follows:

Dear Doctor Emerson:

Thanks for your courtesy in transmitting the copy of the resolution

adopted by the International Association of Ice Cream Manufacturers in Chicago, September 18, 1933. As Chairman of the newly organized Committee on Standard Methods for the Examination of Dairy Products of the American Public Health Association, I wish to emphasize the suggestion contained in this resolution that all laboratories following procedures in analyzing dairy products that they regard as superior to those outlined in the new (sixth edition) of *Standard Methods of Milk Analysis* (in press), transmit a description of these improved procedures to the undersigned. Such suggestions will receive careful consideration by the committee. It is only through the helpful coöperation of interested laboratory workers that this report is kept up to date.

If, on the other hand, laboratories find that they are following out of date recommendations, it is suggested that these procedures be brought into harmony with standard procedures as quickly as possible. Even where laboratories follow standard procedures closely, there are still enough discrepancies in counts obtained from duplicate

samples of milk and cream sent to different laboratories to give continued support to those interests that try to undermine confidence in bacterial counts by attacking their accuracy.

Plans are already under way for making an extensive comparative test of the suggestions that have been made that the standard incubation temperature be reduced from 37°C. to 32°C.; and that the composition of the agar be changed

to one more suited to growing all types of bacteria known to occur in market milk and ice cream. It is hoped that agreement can be reached in regard to these matters before the next edition of the *Standard Methods of Milk Analysis* is prepared.

VITAL STATISTICS

The Incidence of Venereal Disease in the United States—If the incidence of venereal disease can be reduced by adequate sex education, a large proportion of our population would be protected against a very important cause of mental deterioration. According to Vedder, 20 per cent of the young adult males of the population of the class from which the army was recruited are infected with syphilis and 5 per cent of the young men in colleges. The syphilis rate for the country is generally represented as 4.77 for the males and 3.07 for the females, with the highest prevalence among young adults twenty to twenty-five years of age. What is more significant for the welfare of the people is that syphilis permeates all strata of our population. The statistics of the American Social Hygiene Association, based upon blood tests, show figures varying from 1.4 per cent for farmers to 3.2 per cent for merchants and tradesmen, 6.1 per cent for laborers, and 11.7 per cent for railroad employees as recorded at the Mayo Clinic. Stokes and Brehmer assert that 26 per cent of syphilitics become infected between the ages of seventeen and twenty years and 32 per cent between twenty and thirty-five years of age. According to the studies of Newsholme, 10 per cent of all admissions to the state hospitals for the insane are due to general paresis. If syphilis is present in the general population to the extent of 10 per cent, the potential hazards to rational mental function are severe. To state that each year the United States presents a minimum of 679,000 new cases of gonorrhea and 423,000 new cases of syphilis is a sharp challenge to the intelligence of communities that em-

ploy every effort to educate the public concerning diseases like rabies, tuberculosis, and typhoid fever. These diseases are relatively negligible in their effects upon somatic and psychic well-being compared with the absolute and relative ravages of the venereal diseases.—*Mental Hyg.* 18:45 (Jan.), 1934. (Taken from *Sex Education in Relation to Mental and Social Hygiene*, by Ira S. Wile, p. 40–50.)

Vital Statistics for Maryland—A provisional summary of vital statistics for the State of Maryland in 1933 shows that 27,633 births were reported in the state during that year, as compared with 28,740 in 1932. The birth rate decreased from 17.2 in 1932 to 16.3 in 1933, the lowest rate on record. There were 21,464 white births and 6,169 colored. Of the total 27,633 births about 11 per cent were attended by midwives.

The general death rate continued the uninterrupted downward trend which has characterized it since 1928. In 1932 the rate was 12.6 per 1,000 population, and in 1933 it was 12.2. The white population had a mortality rate of 11.3 and the colored a rate of 16.5. Almost 70 per cent of the deaths occurred among persons 45 years of age and over.

The infant mortality rate for Maryland for 1933 was 64.9 per 1,000 live births, as compared with 69.5 for 1932. The low rate for 1933 is noteworthy because it is considerably lower than Maryland's previous lowest rate which was the rate recorded in 1932. In 1933, 1,149 white infants died as compared with 644 colored, making the mortality rate for the white infants 53.5 and for

the colored, 104.4. It is interesting to note that more deaths occurred during the first month of life than in all the rest of the first year, and that congenital malformations and diseases of early infancy caused 53 per cent of all the infant mortality. Of the 23 counties in the state, Queen Anne's (with an infant mortality rate of 120.2), Worcester (110.8), and Somerset (108.9), had the highest infant mortality rates and Carroll (38.0), Baltimore (44.8), and Howard (45.1), the lowest. There were 135 puerperal deaths in 1933 as against 144 in 1932. The maternal mortality rate per 1,000 live births for this year was 4.4 for white mothers and 6.6 for colored.

Analysis of the individual causes of death in 1933 shows that typhoid fever (with a death rate of 2.2 per 100,000 population), diphtheria (1.7), and tuberculosis (80.6), had the lowest mortality rates ever recorded for these diseases in Maryland. There were decreases for 1933 over 1932 in the mortality from measles which declined from 1.1 to 0.2, whooping cough from 5.4 to 4.9, influenza from 20.1 to 17.2, diabetes from 25.7 to 23.6, diarrhea and enteritis under 2, from 19.6 to 16.7; and marked reductions in cerebral hemorrhage from 112.6 to 95.1, and pneumonia from 103.5 to 93.8. Heart disease showed a very slight decline from 256.5 in 1932 to 256.0 in 1933.

Scarlet fever was the only one of the infectious diseases listed in the preliminary report, which showed an increase in 1933 over 1932, the rates being 2.3 and 1.9 for the two years, respectively. Nephritis increased from 138.5 per 100,000 in 1932 to 144.4 in 1933, and automobile accidents from 24.2 in 1932 to 25.4 in 1933.

Heart disease, nephritis, cancer, and cerebral hemorrhage were the leading causes of death in the State in 1933, and together they caused 50 per cent

of the total mortality.—Maryland State Department of Health. Bureau of Vital Statistics (Jan. 15), 1934.

Statistics on Obstetric Operations in Hamburg, Germany—Statistics compiled by the public health service on obstetric operations performed in the city of Hamburg, Germany, reveal that in this city with a population of 1,100,000, a total of 5,391 births were completed with the aid of an operation, during the three years 1929–1931. Since, during that period there were 46,401 births (inclusive of stillbirths), there were 116.1 obstetric operations per thousand births. The figure 5,391 included 3,654 obstetric operations such as forceps delivery, version, extraction, embryotomy, perforation, induced premature birth and caesarean section, and also 1,737 cases with operative aid in such complications as hemorrhages, placenta praevia, eclampsia, and post-natal complications.

Compared with the prewar period, the number of births completed by operation shows a marked increase: for instance, during the period 1910–1911, a total of 3,488 obstetric operations were performed in Hamburg. These included the complications of the birth process but did not include aid given in hemorrhages, and represented 8.05 per cent of the total number of births. Aside from the birth complications, obstetric operations were performed in 2,854 cases, or in 6.50 per cent of the births.

The distribution of the obstetric operations has undergone a change as compared with the prewar period. Podalic version has declined to about half of its prewar frequency. Artificial induction of premature birth was not reported in 1929–1931 in a single instance. Embryotomy has increased from 2.1 per cent to 3.3 per cent. Caesarean section has increased to an even greater extent. During the period

1876-1880, caesarean section occurred only once in a thousand obstetric operations performed in Hamburg. In 1910-1911 the proportion increased to 13 per thousand; in 1929-1931 the proportion rose to 176 per thousand. For the most part, caesarean section was substituted for version. A period of fifty years has brought a 350 fold increase in the use of caesarean section. In the early history of the revived operation (for example, in 1881-1885), 75 per cent of the mothers succumbed to the operation; in 1910-1911, only 18.2 per cent; and the mortality has since decreased steadily.

The mortality of other obstetric operations has likewise declined, although not to the same extent. The percentage of stillbirths resulting from the use of forceps has changed the least (1910-1911, 6.0 per cent; 1929-1931, 5.1 per cent). With respect to version, the decline in mortality over this period has been something more than one-third

(from 38.5 per cent to 24.5 per cent); as regards extraction, a little more than one-fourth (from 20.9 per cent to 15.1 per cent). Taking obstetric operations as a whole, the danger of a stillbirth has declined from 18.0 per cent to 13.4 per cent, or about one-fourth, which has been brought about chiefly through the improvement in the technic of caesarean section.

The complications of labor have become more frequent: 1910-1911, 1.45 per cent; 1929-1931 (without hemorrhages), 1.97 per cent. Various complications make up the increase, but particularly eclampsia which increased from 0.09 per cent to 0.34 per cent.

With respect to stillbirths, in 1910-1911, 61.5 per cent of the babies were born dead in association with placenta praevia; in 1929-1930, only 19.4 per cent. In eclampsia, the infant mortality has declined from 25 per cent to 12 per cent.—*J.A.M.A.* 102:224-225 (Jan. 20), 1934.

PUBLIC HEALTH ENGINEERING

THE AIR WE BREATHE AND THE SOUNDS WE HEAR*

JOEL I. CONNOLLY, F.A.P.H.A.

Chief, Bureau of Public Health Engineering, Board of Health, Chicago, Ill.

THE importance of the air we breathe with respect to public health warrants the serious attention being given to it in any consideration of the public health engineering problems of large communities. A person may live for weeks without food, and for days without water, but he cannot live more than a few minutes without air. For this reason, a continuous supply of air is more important to life than a continuous supply of either food or water.

If we do not like the water or food at the place where we happen to be at the moment, we can wait for a reasonable period until some other source can be procured. But we do not enjoy this much latitude with respect to air. We have to breathe the air wherever we may be, and have no option in the matter.

A due recognition of these facts has led to a tremendous development of air conditioning apparatus in recent years. Devices for efficient and controlled heating, cooling, humidifying, and dehumidifying, as well as the removal of dust and other air impurities are now available for all types of buildings. This last summer a considerable amount of prominence was given to air filters for private homes for the prevention and relief of hay fever.

The construction of many of the

buildings at "A Century of Progress Exposition" points the way to possible trends in the housing of the people in large communities. Advances in artificial lighting and mechanical ventilation have made possible the use of windowless buildings, providing comfort to visitors, and permitting a better utilization of wall space because of the lack of windows. The constancy of the lighting on exhibits as a result of this arrangement has been a large factor in reducing eye fatigue, which was so objectionable in many museums and expositions of an earlier day. Such windowless buildings would be out of the question were it not for the modern appliances available for maintaining the air in a condition conducive to health and comfort.

On the other hand, some buildings erected at the World's Fair have walls made entirely of glass. Here we have the two extremes—the windowless building and the house which might be called "all windows." Even in these glass houses, mechanical ventilation has been used to control the air conditions so that the windows need not be opened. In this way, better control may be maintained over the temperature and humidity of the air inside the building, and dust and odors may be excluded.

The provision of proper air conditions in buildings used as the homes and workshops of the people in large communities is far more than a mere mechanical or engineering problem. It

* Presented before the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 16, 1935.

is largely a social and economic problem as well. Complete air-conditioning apparatus cannot be afforded today by large sections of the population, so we must assure sufficient natural ventilation by judicious city planning, zoning restrictions on overcrowding of buildings upon the available land, and by suitable provisions in the building code regarding the size of windows, ceiling heights, and similar factors.

Another important consideration, especially in small homes, is the lack of any assurance that air-conditioning apparatus, if installed, would be maintained in an operating condition after the buildings became old and rundown. It is the experience of large cities that as soon as the profits from any building dwindle, the management is prone to economize by restricting the operating of ventilating equipment, and by failing to make the necessary repairs and replacements of essential parts of the equipment as they wear out.

For this reason, it is my opinion that public health engineers should oppose efforts to substitute mechanical for natural ventilation in small dwellings. It is probable that large buildings can make use of artificial air supply and lighting for interior rooms to advantage when the high achievements of these two arts are considered.

The air in factories and workshops is subject to contamination with many substances, some of which are dangerous to life. There is a tendency to use new materials and processes which offer the prospect of lower production costs and increase profits, without first taking the time and trouble necessary to determine what effect the change will have upon the health of the workmen exposed to the new substances. Frequently, definite information upon the physiological reaction of an individual to a substance is sadly lacking, and the manufacturer does not know where to turn for authoritative informa-

tion. Under these circumstances, he is likely to assume that there is no hazard and commence use of the new material.

Not infrequently the toxic effects are slow in making an appearance, whereby they may be recognized, and a false sense of security may be built up, as was the case with methyl chloride in domestic refrigerators. We have found that very small concentrations of other halogen compounds, such as carbon tetrachloride for example, may be toxic to workmen exposed to them for 7 or 8 hours a day over considerable periods. The amounts of these substances which produce illness are very much less than the toxic limit as given in the literature based on experiments involving only a short exposure.

The great strides which have been made in chemistry in this country during and since the war have made available to our manufacturers a wealth of substitutes for toxic materials, so that today there is little excuse for any industry to use substances that are highly toxic to the workmen. For example, in many places, xylol, toluol, and petroleum distillates have been substituted for benzol as a solvent for rubber, lacquers, enamels, and other substances. Titanium oxide and lithophone are being substituted for the more toxic lead in paints in order to reduce the hazard of lead poisoning.

One danger to be guarded against, is the possibility that unforeseen conditions may create a wholly unexpected health hazard against which no protective measures are being taken. For example, a recently developed refrigerant, dichlorodifluoromethane, has been declared by its users to be ideal because of its inert character and its favorable physical characteristics, such as the boiling point. This material may decompose in the presence of a flame, forming the dangerous gas, phosgene. A carbon tetrachloride fire extinguisher

if used in an atmosphere poor in oxygen may permit the formation of the same substance. Public health engineers must learn to recognize the possibilities of such occurrences and to guard against them.

It may be that studies now being made and the example set by the exhibit buildings at the World's Fair may result in a new conception of housing people in great cities. The use of new materials and new adaptations of old materials, together with the emphasis upon plain, unadorned surfaces, the use of color, and the relation of masses may have a decided bearing upon the architecture and mode of construction of the homes and workshops of the future.

It is probable that people would be better housed if cheaper and less permanent forms of construction were employed for erecting houses having a useful life of 10 or 15 years. The advances to be anticipated during the life of the buildings would warrant their demolition at the end of that time, and the erection of new, more healthful, and more comfortable dwellings in their place. Of course, the financing of such a scheme would be dependent upon reduction of costs, and perhaps also to some extent upon factory fabrication, as well as mass production.

The public health engineer is eminently fitted by training and experience to take a leading part in such a movement, with the object of removing existing insanitary and unhealthful dwellings and replacing them with houses where health may be properly safeguarded at little or no additional cost. A danger to be guarded against is the sweeping aside of health considerations in an effort to cheapen buildings. This must not be permitted, as it is false economy, penny-wise and pound-foolish, and the members of this Association should be on the alert in their own communities to detect trends

in that direction and combat them with every means available.

There remains the question of outdoor air. When one travels from the uninhabited mountain peak or primeval forest to a city, he expects to encounter an increasing amount of air contamination, even outside of buildings. Heating plants, chemical and fertilizer factories, packing plants, steel mills, oil refineries, smelters, coal yards, cement mills, restaurants, power houses, railroads and steamships, all contribute their quota of smoke, ash, dust, fumes, gases, and obnoxious odors.

Some of these materials affect the human body directly, such as arsenic compounds from smelters and foundries, acids from metal plating works, and sulphur compounds from many sources. Perhaps the most widely known example of this direct action is the poisonous fog which settled in a river valley in Belgium in December, 1930, and caused 65 deaths. Investigation revealed that these deaths were due to sulphurous anhydride gas from a nearby industrial district. That occurrence received widespread attention because of its dramatic suddenness and the imaginative theories expressed in the newspapers connecting it with hidden stores of war gases.

The higher pneumonia death rate in urban than in rural districts has been blamed by some upon the inhalation of toxic substances in the air, which contribute to a premature death as surely, if not as quickly, as in the Belgian incident.

At the Fort Worth meeting of this Association, Dr. Fred O. Tonney and Clarence R. De Young¹ described the correlation between pneumonia deaths and ultra-violet radiation in the sunlight, showing that a decrease in actinic rays was followed, a month or two later, by a corresponding increase in the pneumonia death rate. It is possible and even probable that the

increase in contamination of the air by smoke and ash, which serves to cut down the ultra-violet light in winter, also affects the individual directly, thereby having a double-barrel effect upon the unfortunate victim.

When one considers that great attention is paid to the purity of water, milk, oysters, and other food, while the amount of gaseous and solid waste discharged through chimneys and stacks has largely increased with the growth of cities and industries, it is easy to see how greater amounts of harmful substances may enter our bodies in the air we breathe than in the food and water we swallow. Many people do not realize that from 4 to 7 times as much air, by weight, enters our bodies, as food and water combined.

The effect of air contamination upon our greatest natural germicide, the sunlight, is doubtless an important factor in the spread of common communicable diseases during the winter. Of course, the rôle of sunlight in preventing rickets is too well known to need comment here. In spite of the ease with which rickets may be prevented, it is still too common, and sometimes found where you would least expect it.

Contamination of the air with carbon monoxide on and adjacent to heavily travelled boulevards and streets is a factor to be reckoned with in promoting vitality and adequate resistance against disease. Only those who suffer with hay fever fully appreciate the importance of keeping out-door air free of irritating pollen by destroying weeds before they pollinate.

Smoke has created another hazard to life since the birth of aviation, namely, the poor visibility over cities where air lines center. A great deal of discussion has occurred in Chicago, for example, as to the feasibility of creating an airport on the lake front near the heart of the city, the greatest drawback to the proposed location be-

ing the poor visibility occasioned by smoke. Thus far this objection has been serious enough to prevent undertaking the project.

Many devices are in use to reduce the contamination of out-door air. Some aim at more complete combustion of fuel to eliminate soot and black smoke, but do not always prevent blowing large amounts of ashes and fine cinders from the stacks. Other devices reclaim valuable products from the gases emanating from such places as refineries for precious metals and smelters. These may be various forms of filters or Cottrell precipitators, using the well known repellant action of similar electrically charged particles. Washers and scrubbers are widely used for removing dust and acid fumes, and chlorination has been used successfully to control objectionable odors from garbage reduction plants and similar places.

One other form of health menace reaching us through the medium of the air remains to be considered briefly—noise.

The growing mechanization of industry and transportation, and the development of radios and amplifying systems have greatly increased the noise of which large communities are victims. This problem must be considered in two sections: (1) the noisy industries where re-design of machinery for more quiet operation is possible; and (2) community noises which are the sum-total of many minor noises.

The former can be minimized by properly directed industrial hygiene work, pointing out to employers the losses of accuracy and efficiency occasioned by a noisy environment, the high cost of replacing employees unable to stand the continued wear and tear on their nervous systems, and the losses due to deterioration of machinery.

Studies have indicated that the cost to an industry of replacing even a common laborer is \$25, and this cost rises

rapidly with the degree of skill required of the employee. Added to these direct costs to industry, there are the burdens imposed upon all taxpayers for the maintenance of institutions for those suffering from nervous and mental diseases. These conditions are particularly affected by noise.

The second classification of community noises can better be dealt with by education of the public as to the benefits accruing to themselves and their neighbors as the result of maintaining a reasonable degree of quiet. Certain things, such as the sale and discharge of fireworks, may perhaps be controlled by laws; but there are so many other sources of noise which are parts of the grand total that it would be impracticable to make and enforce laws to prevent all of them. Therefore, education is the principal weapon to be used in fighting them.

That the public is becoming noise-conscious is reflected by advertisements of apartment buildings which stress the fact that the building is sound-proof rather than the desirability of location or other features calculated to attract tenants. An article appeared a few days ago in a large metropolitan newspaper headed, "Court O.K.'s Purchase of Silent Cars." This item stated that the court had authorized the receiver for a street car company to purchase some new cars, and the feature of these believed by the newspaper to be most interesting to the public was the quietness of their operation.

It is my opinion that there will be an increasing amount of attention given in the near future to preventing unnecessary noises at their sources by better design of machinery and switching from noisy to quiet operations, as, for example, from riveting to welding of steel structures. In this movement, too, the public health engineer should take an active part to stimulate progress along the proper lines and assure that

the nervous systems of our people are given as much consideration as their freedom from communicable diseases and protection against the hazards peculiar to childhood.

CONCLUSION

There is danger that we may become hopeless and apathetic toward the hazards to health involved in conditions of the air, such as noise and contamination by toxic and otherwise objectionable substances, both inside and outside of buildings, because of the immensity of the problems and the rapidity with which new aspects arise with the development of new processes and industries.

Although progress has been made in some directions, the degenerative diseases stand out as unconquered obstacles to attaining the aim of public health work, prolonging life and making it richer, more useful and happier while it lasts. How much of these degenerative diseases can be prevented by improvement of the environment may be difficult to predict, but there is no lack of medical authorities who suspect a connection between lung cancer and the tar in soot. Nephritis is doubtless promoted by the toxic substances absorbed during the course of early and middle life, even though it may not definitely develop until later. It is safe to say that continued progress in public health protection must include some measures directed against the present principal causes of death.

We must bring to bear on these problems of the atmosphere the same careful thought and investigative attitude that have been responsible for the outstanding progress made in some other lines of health protection, such as in treatment of water supplies or reduction of infant mortality. We must keep ever before us the fact that the health hazards present in the air we breathe affect the entire population regardless

of age, and in this respect they transcend in ultimate effect those dangers limited to any one group or age.

Two things appear to be outstanding needs of the moment—(1) more authoritative information and (2) education of the public in order to secure enthusiastic and voluntary coöperation in the reduction of the health hazards. Fundamental data such as those collected by the U. S. Public Health Service, Mellon Institute, New York Commission on Ventilation, American Society of Heating and Ventilating Engineers with the United States Bureau of Mines, the National Safety Council, and the Local Safety Councils, the American Society of Mechanical Engineers, the Acoustical Society of America, this Association and others, are greatly needed, to envisage the seriousness and extent of the problems and to point out the most effective and economical solutions. The former lack of uniformity of opinion about the relative merits of natural and mechanical ventilation in schools and similar locations is just one example of the need for more extensive and complete information, and facilities for interchange of views.

This Association should endeavor to stimulate the collection of such needed data and use its influence to encourage research work by public health agencies and other institutions and the

financing by industries of studies relating to the health of their workers, neighbors, and the consumers of their products.

Effort to improve housing, both through the Public Works Administration for the relief of unemployment, and in other directions where such agencies are not operative, should be definitely promoted by the Association as such, and by the Fellows and members as individuals. New life should be injected into the campaign to secure an alert and informed public opinion to assure that the scientific data obtained is made effective in its application to health problems of communities, large or small. We should first devote our own zeal to the work and then get all of our fellow citizens to do likewise.

Only in this way can we hope to do more than scratch the surface of the serious and increasingly complex health problems presented by air conditions in the great urban centers in which so many Americans have chosen to establish their businesses and homes.

NOTE: This is the final article from the Symposium on Public Health Engineering Problems of Large Communities (see this *Journal*, Jan., pp. 64-67; Feb., pp. 108-121, and 158-160).

INDUSTRIAL HYGIENE

New Clinic for Occupational Diseases—New York University and Bellevue Hospital Medical College has opened a special clinic for occupational diseases, with a laboratory equipped for the work. Cases of lead poisoning, silicosis, occupational dermatoses and benzene poisoning have already been handled in the clinic, which meets Wednesday afternoons. Physicians and industrial health workers have been invited to refer cases.—*J.A.M.A.* 101, 26:2057 (Dec. 23), 1933. E. R. H.

Tercentenary of the Birth of Bernardino Ramazzini — The entire monthly issue of *Rassegna Della Previdenza Sociale* (Anno XX, N. 10, Oct., 1933, 114 pp.) is devoted to the papers and reports connected with the celebration of Ramazzini's birth—"the father of industrial medicine." Papers were presented by the following professors: Luigi Devoto, Cesare Biondi, Luigi Carozzi, Giuseppe Francioni, Cesare Giannini, Giovanni Lorica, Giuseppe Marangoni, Giovanni Mauro, Antonio Mori, Gaetano Pieraccini, and Gustavo Pisenti. The celebration was held at Milan on October 4, 1933. The papers all pertained to the different activities of Ramazzini, who, in some respects, apparently lived some 300 years in advance of his time. E. R. H.

VII International Congress on Industrial Accidents and Diseases, Brussels, 1935—Announcement has just been received from Dr. L. Dejardin, Secretary-General, of the plan to hold this Congress in mid-July, 1935. As customary it will be divided into two sections representing the International Congress on Industrial Accidents and

the similar Congress on Labour Medicine, both meeting together. Chairmen, so-called "Presidents," have been set up for the various countries who are to proceed to give publicity to the Congress and to organize delegations to attend. Emery R. Hayhurst, Ohio State Health Department, Columbus, has been designated Chairman for the American Delegation for the Section on Industrial Diseases and those interested should communicate with him directly. E. R. H.

Robert Prosser White, M.D., Edin. (Obituary)—Dr. Prosser White, who died at Southport on Jan. 4 at the age of 78, had won for himself an international reputation in industrial diseases. He took his medical degree from Edinburgh University in 1878. He was appointed a certifying factory surgeon in August, 1896, and published a paper on nitro- and dinitro-benzol poisoning at that time. An appointment as physician in charge of the skin department at the Royal Albert Edward Infirmary gave him first-hand knowledge of the skin affections associated with the local industries, and in 1915 he published the first edition of his work on "Occupational Affections of the Skin" which appeared as a greatly enlarged edition some 10 years later. He was an Associate Editor of the *Journal of Industrial Hygiene*. He possessed a large capacity for work, and maintained his keenness throughout a long life; he did not regard himself as a great clinical dermatologist, but rather as a collector of information. It was thus that he started in October to attend the tercentenary celebration in Milan of the birth of Ramazzini, whom he admired

for his spirit of adventure and inquiry. Ill health prevented his attending this celebration, but the substance of his address appears on page 114 of the *Lancet* for January 13, 1934. He gave to the library at Wigan, his native town, a number of sixteenth and seventeenth century works on dermatology and the occupational diseases.—*Lancet*, 5759: 111 (Jan. 13), 1934. E. R. H.

Tenth Anniversary Moscow Institute of Professional Diseases—This celebration is in the name of V. A. Obuch. The Institute was founded by the Section of Common Health of the Council of Moscow, July 23, 1923, being the first of its kind in the Union. The Institute studies systematically the professional diseases in the industries of Moscow for the purpose of promoting industrial hygiene, improving the general health through the organization of medical and prophylactic work, the listing of properly skilled physicians, and education procedures.

During the ten years of its existence, the Institute published 32 collections of its works and 690 articles, some appearing abroad, also a series of pamphlets, leaflets and placards.

At present, the Institute has the following divisions: (1) Professional Hygiene for studying special branches of industry, each of which has its doctor of hygiene, promotes the selection of proper workers, etc. A comprehensive laboratory is provided for research and tests. (2) A Clinic, having 250 beds, also has laboratories and relates clinical findings with industrial influences. One section with 30 beds, called a half-way station, permits aptitude tests. Another section, with 25 beds, specializes in the selection of young workers. (3) The Physiological Laboratory is one of the largest in the Union. This concerns itself with both the theoretical questions of industrial physiology and those of experimental toxicology.

The various industrial plants are represented in the Institute where workers also take an active part in the deliberation of questions extant.

"Informing you of its anniversary, the Institute hopes that this celebration will serve to unite the specialists of (the) professional hygiene and pathology working in the different countries." The statement is signed by Arnautoff, as Director of the Institute, and Smirnoff, as President of the Jubilee Commission. E. R. H.

Japanese Institute for Science of Labour, Annual Report, 1932—This lists researches finished in 1932 such as environmental conditions, rationalization of labour, fatigue researches, qualification of workers, and occupational diseases. There follows a list of lectures and reports at various meetings and congresses.

The bulk of the report is devoted to abstracts of papers published in *The Journal of Science of Labour*. There is also published a Japanese Year Book of Social Hygiene, while 5 of the major papers published in 1931 and 9 of those published in 1932 have been translated into English and German, and appear in the Journal of the Institute. Some of the workers have been students in American educational institutions.—Gito Teruoka, Director, Kurasaki, Japan, July, 1933, 25 pp. E. R. H.

Report upon the Work of the Miners' Phthisis Medical Bureau for the Three Years Ended 31st July, 1932—This is an extensive, long page, closely printed report with tables and schedules, too extensive to abstract, but treated under various subjects such as: pathological and other investigations, the exactions required in the examination of workmen having in view compensation matters, silicosis (with an extensive discussion), likewise tuberculosis, benefits and beneficiaries, Euro-

pean and native laborers, etc. The report is by Dr. L. G. Irvine, Chairman.—Union of South Africa, April 13, 1933, 62 pp. (Procurable from the British Library of Information, 270 Madison Avenue, New York, N. Y., price 3s. 6d. Code U. G. No. 22, 1933. 3804--3/6/33--750.) E. R. H.

Abstracts of the Reports of the Institute of the Science of Labour, Japan—These abstracts are rendered in English and are taken from the *Journal of the Science of Labour*, Vol. 5, No. 1-5, first half of 1928. The pamphlet (9 pages) abstracts 17 papers pertaining to the physiology of the worker, the effects of the environment upon him, intelligence tests, and measurement of norms.—Kurasiki, Japan (received 1933). E. R. H.

Eighth Annual Report, Ontario Department of Health, for the Year 1932 (Industrial Hygiene Branch)—The personnel of the Industrial Hygiene Branch consisted of a Director, Clinical Specialist, Special Research (Worker), Chemist, and Chief Sanitary Inspector. The demands upon the facilities of the Branch or Division have considerably increased in spite of industrial unemployment, due no doubt to the emphasis upon sickness from the economical standpoint and that labor turnover is reduced to a minimum. Also, voluntary health work by employers has but seldom been discontinued, which would suggest that the procedure rests upon a sound basis.

Special discussion pertains to: (1) ventilation, in which it is found that overheating in winter is the most common failing; there is no satisfactory evidence to support the claim that increased humidity has a beneficial effect on healthy people, while there are also no data showing a relation to exist between the incidence of sickness and ventilation conditions, so that the use of

sickness experience as a general indication of ventilation appears not to be warranted. (2) Occupational diseases; at the last session of the Legislature, are required to be reported by all physicians and to the Provincial Department of Health, where it has been found that thus far suspected cases of lead poisoning and silicosis predominate. (3) Surveys made of trades or occupations with exposure to silica dust, particularly foundries and vitreous enamelling, also the examination of rubber workers exposed to talc dust, others exposed to marble dust, the examination of 168 contacts (wives and children) of miners with silicosis and tuberculosis, with direct evidence of spread; the examination of a rubber shoe factory with the suggestive evidence that the inhalation of fumes of gasoline or like solvents assists the development of tuberculosis; and the increased physical examinations made necessary through the new regulation of the Factory Act. (4) The control of dust and fumes with caution in regard to the installation of ineffective equipment, also the surveying of the potential hazards in a considerable number of plants in various industries. (5) The work of the industrial hygiene laboratory—estimation of the amount of lead in the air, autopsies, the discovery that in a number of incidences neither the employer nor the employee was aware of the constituents of hazardous materials used. (6) First-aid and health posters. (7) Fumigation with cyanide compounds, attended with 6 fatalities during the year. (8) Sanitary inspection, particularly in relation to lumber, timber, and mining camps.

A separate leaflet embodies regulations of the Factory, Shop and Office Building Act, adopted Sept., 1932, particularly pertaining to the industrial use of benzol and lead and requiring that all manufacturers, distributors, employers, using substances dangerous to

health "when required by the Chief Inspector of Factories on advice of the Director of the Division of Industrial Hygiene, must post in a conspicuous place printed forms to be approved by the Department of Health setting forth these dangers and indicating the precautions necessary for the protection of their employees."—Dr. J. Grant Cunningham, Director, Division of Industrial Hygiene, *The Report*, pp. 36–40 (plus leaflet mentioned). E. R. H.

Occupational Poison and Disease Statistics, New York State Division of Industrial Hygiene, Jan.-June, 1933—This typewritten report comprises 3 tables, the first of which shows the make-up of the 402 claims from New York City and "Up-State"; the second, the causes arranged in alphabetical order by months; and the third, the leading causes, in a general summary. Of the 402 cases, 20 had a doubtful classification, and 58 were not in the schedule (of compensable diseases). The leading causes in the compensable list were, with cases, lead, 40; benzol, etc., 39; carbon bisulphide, 10; tetrachlorethane, 14; chrome, 9; carbon monoxide, 17; acids, 9; petroleum products, 13; friction, 17; dermatitis, 141 (acids 5, alkalies 70, oil 45). Notable causes in the non-compensable list were: carbon tetrachloride, 7; dermatitis, non-scheduled, 21; diseases, non-scheduled, 19; dyes, unspecified, 9; dyes, specified, 7; hydrogen sulphide, 10; lacquer, 5; poison ivy, 35 (possibly scheduled); trisodium phosphate, 4; turpentine, 4.—J. D. Hackett, Director, 40 Centre Street, New York City.

E. R. H.

Child Labor Under the N. R. A.—The National Recovery Administration has adopted the principle that a 16-year minimum age for full-time employment should prevail throughout industry. Over a hundred permanent

codes of fair competition have been approved and were in effect by November 15, 1933. These include many important manufacturing and mining industries and most of the retail dealers. The codes prohibit the employment of children under 16, with the exception of the general retail code which permits children between 14 and 16 to work part time outside school hours; 18 has been fixed for a number of dangerous industries or for certain hazardous processes. Through these codes a real beginning has been made in restricting child labor. Much, however, remains to be done, particularly in securing a more complete coverage of dangerous occupations by the higher age standards. Furthermore, certain forms of child employment—e.g., in street trades, domestic service, and commercialized agriculture—will be difficult to regulate under the National Recovery Administration.

The article details further relationships of this question as regards various trades, vocational guidance, legislation, etc.—U. S. Children's Bureau, *Child-Welfare News Summary* (Nov. 24), 1933. 8 pp.

E. R. H.

Sickness Among Male Industrial Employees in the Third Quarter of 1933—The reports of industrial sick-benefit associations show a lower rate of sickness causing disability for 8 consecutive days or longer per 1,000 men during July, August, and September. The rate was 65.3 as compared with 77.0 in the third quarter of 1932 and 88.8 in the corresponding quarter of 1929. Both respiratory and non-respiratory diseases were decreased, in the quarter under discussion.—Dean K. Brundage, B-268, U. S. Public Health Service, 3 pp.

E. R. H.

Insulation Against Heat and Cold for Human Comfort—A study was made of the uses of bright metallic surfaces since they reflect much of the

heat they receive. The method of insulation also took into consideration the low heat-conducting properties of air and the fact that an air-proof material hinders the passage of heat by convection currents. Briefly, the insulator is a sheet of reinforced aluminium foil—*i.e.*, material covered on both sides with aluminium foil—fixed so as to divide the air space across which the transference of heat is to be hindered. Laboratory tests were first made at the London School of Hygiene and Tropical Medicine and then followed up for practical experiences in Egypt, also on ships, and in tents, trains, and ambulances. A tropical helmet was devised which also proved its efficacy.—G. P. Crowden, *Lancet*, 5758:37-40 (Jan. 6), 1934.

E. R. H.

Report of Industrial Hygiene Committee, State and Provincial Health Authorities—The control of occupational diseases is fundamentally a public health problem. The efforts of public health organization, it should be appreciated, will be rendered less effective unless adequate attention is given to the large groups of industrial workers. The relations are significant in regard to the so-called "degenerative diseases," and the influence upon same of dangerous or unwholesome environment. Evidences to this effect are noted by Dublin in the mortality experience of this group in which, *e.g.*, it is shown that a 20-year old worker engaged in the non-hazardous occupations has a life expectancy seven years longer than the "industrial worker" beginning at the same age.

The industrial hazard situation may be said to simulate an epidemic with the focus of infection in the contaminated workroom. Just as public health authorities have learned the necessity of providing well trained men to locate and eliminate the source of an epidemic, a no less well organized bureau should

be considered for the elimination of the source of the occupational disease. The importance of the subject is manifested by the growing interest in industrial hygiene in the various states, such as the adoption of codes specifying the maximum amount of toxic material to which workers may be exposed. Likewise a number of universities have seen fit to provide special courses in industrial hygiene.

Any program for the control of occupational diseases necessitates:

1. Reporting and investigation of cases.
2. A comprehensive knowledge of the effects upon health of materials and processes used in industry.
3. Physical and chemical determinations of industrial environments.
4. Laboratory facilities.

The health department, made up of its different types of workers and functions, provides the basic facilities and technical staff necessary for the control of occupational diseases.

The industrial hygiene activities of health agencies was inquired into by means of a questionnaire with a summary by states, including Connecticut (surveys, special studies, and lists of hazards); Indiana (a brief statement of some limited investigations by the Division of Industrial Hygiene); Michigan (discontinuance of its Bureau of Industrial Hygiene due to lack of funds); Mississippi (health and educational program); Ohio (suggestion of points to be stressed); Ontario, Canada (with brief statement of its major activities); Rhode Island (liaison with the factory inspector and the contemplation of organizing a Division of Industrial Hygiene).

The American Public Health Association has 8 committees active in industrial hygiene (consult annual *Year Book* for reports). The U. S. Public Health Service, through its Office of Industrial Hygiene and Sanitation, lists a number of important activities.

A brief discussion follows by certain states.—Stanley T. Osborn, Chairman, *The Proceedings*, 47th Annual Meeting, Washington: 149–155 (June 2–3), 1932.
E. R. H.

Ventilation, Sunshine, and Clothing—This is a comprehensive article based largely upon animal experiments, including guinea pigs, rabbits, pigeons, and monkeys, and the conclusion was reached that properly fed animals remain remarkably free from disease under various environmental conditions, while improperly fed animals, however well kept, are remarkably subject to it. Heat-stroke and its avoidance was a feature of investigation as well as control of epidemics by ventilation, such as the spreading apart of beds and opening the windows of dormitories as advocated by Captain S. F. Dudley. Thus infection cannot be stopped by isolation of the sick; but it can be enormously reduced by good ventilation. The cubic space of a room is of no importance; it is the ventilation which counts. The dusty, warm atmosphere of crowded rooms not only spreads infection but lessens the defence of the membrane which lines the breathing passages. Every sedentary worker can devote some of his spare time to open air exercise.—Leonard Hill, *Lancet*, 5747:933–936 (Oct. 21), 1933.

E. R. H.

Occupational Disease Hazard of Silicosis in Construction Operations and Its Prevention—This paper is based on approximately eight years' definite personal study of the effect of underground dusts on health and safety, supplemented by about 25 additional years of close attention to data and studies made by others. The author has conducted intensive study in more than 100 coal and metal mines and in scores of mining communities in twenty-five states, first as a mine surveyor, then

as a coal mine superintendent, and finally with the U. S. Bureau of Mines. The subject is handled from an engineering viewpoint which has convinced him that "stop the dust" is the only feasible solution.

The general physical characters of dust, pathological relationships, the various hazardous operations, the futile and often very expensive installations made by well-intentioned employers, the comparison of foreign experiences, and the fact that after all the real solution lies with the engineer, are all discussed. Rules are laid down for the best procedures and certain citations were made from current literature. A very extensive bibliography is appended, classified as to sources of material, particularly along engineering, mining, metallurgical and related lines.—D. Harrington, 13 pp., from address presented before Construction Section, National Safety Council, Oct. 2, 1933, published by U. S. Bureau of Mines (not coded).

E. R. H.

Silicosis—This pamphlet, profusely illustrated, aims to present to manufacturers a brief description of the disease, its causes and complications, and a more detailed discussion of measures designed to prevent its occurrence.

There are included: industries and processes using silica, a table showing the uses of silica, and the types of silica used in each; harmfulness of silica dust; dust determination; standards of dustiness; how silica reaches the lungs; symptoms and diagnosis of silicosis; the complication with tuberculosis; classification by stages; prognosis; and preventive measures.

The last subject is given special emphasis under the head of protective devices, good housekeeping, medical supervision, the practical application of local exhaust equipment, of segregation and special equipment, and plant surveys. A selected bibliography fol-

lows.—Industrial Health Section, Met. Life Ins. Co. 1933, 32 pp. E. R. H.

Lead-Poisoning, Legislation and Statistics—This bulletin reviews legislation and statistics for lead poisoning in several foreign countries as well as in the United States, and should be consulted in the original for the many valuable deductions made. It is replete with tables and a considerable number of case reports. The statistics pertain to the years 1930–1931, and were partly derived from a questionnaire. The recorded deaths from lead poisoning in the United States for the year 1930 was 99. There is included also a reference to the Reports of the Committee on Lead Poisoning, A.P.H.A., which appear in the annual *Year Book* and elsewhere in the *Journal* for the last several years. The author was Chairman of the Subcommittee on Statistics of this Committee. The concluding portion of the report is the translation of the report of the Swiss Accident Insurance Society (Director Tzaut), made to the Federal Commission on Lead-Poisoning, May 7, 1929.—Frederick L. Hoffman, Consulting Statistician, Prudential Insurance Co. of America, Newark, N. J. 1933, 40 pp. E. R. H.

"Industrial Medicine"—The September, 1933, issue of this new publication (Vol. 2, No. 3) comprises pages 145–204 with table of contents, major papers, industrial hygiene digest, announcements and news.

The major papers comprise the following:

Occupations of Antiquity, by Robert T. Legge (University of California), which in particular discusses the earliest known mention of the various metals and where found, and the earliest references to occupational diseases. The author considers the earliest dangerous trades to have been implement and armor making, the construction indus-

try, husbandry and agriculture (a brief paragraph), the bronze age, metallurgy and mining, the glass industry, and pigments and cosmetics. The article also reviews primitive surgery and industrial hygiene and concludes that the latter subject has been a progressive one and did not "begin with the invention of the steam engine."

"Compensable Back," by Dr. John D. Ellis—the technic of examination; exaggeration and malingering.

Psychology of Trauma, by Dr. Jewett V. Reed (Indianapolis)—classification under the heads of malingering, neurosis following trauma, and mistaking the cause and effect.

Carbon Dioxide—An editorial summary covering its hazards and uses.

Health and Business Recovery, by Dr. Hart Ellis Fisher, Chicago Rapid Transit Company.

One Hundred Books for the Doctor—A special selection of recent titles.

Coal for Industrial Hygiene, by Dr. Dean K. Brundage, Statistician, U. S. Public Health Service.

Vocational Rehabilitation—Its History and Scope of the National Program, by John A. Kratz, chief, Vocational Rehabilitation, Federal Board.

There are also many important fillers.
E. R. H.

Papers in The Industrial Bulletin, New York Department of Labor, Aug., 1933—

The Next Step in Industrial Hygiene—A brief discussion to the effect that there must be a vigorous application of hygienic ideas in industry and especially that relating to the control of dust, fumes and gases at their points of origin.—J. E. Hackett, Sept. issue, p. 200.

Lead Poisoning and the Depression—Essentially a discussion of the nature of lead poisoning and the fact that along with the modernizing of public and industrial institutions must be considered

the inclusion of advanced methods in the protection of workers against lead poisoning.—May R. Mayers, Sept. issue, pp. 201–202.

Review of Silicosis, Part V—The prevention, dust estimations, and educational procedures necessary to cope with this hazard.—Adelaide Ross Smith, Sept. issue, pp. 224–226.

Corrosion in Exhaust Systems—A discussion of the electrolytic and acid theories, illustrated, along with methods of testing materials for equipment in advance of their usage.—John H. Vogt, Oct. issue, pp. 252–254.

Review of Silicosis, Part VI—Silicosis compensation in the United States and requirements of an adequate silicosis compensation law. Under the latter heading, the necessity for a defi-

nition of silicosis and its stages, eligibility for compensation, diagnosis by expert authorities, and the amount of compensation.—Adelaide Ross Smith, Nov. issue, pp. 308–309.

1932 Directory of New York State Manufacturers, Volume II, Metropolitan Area—This is procurable from the New York State Department of Labor, 80 Centre St., New York City, Directory Division, price \$5.00.

Skin Diseases in Industry—Case citations and general discussion.—May R. Mayers, Dec. issue, pp. 314–315.

Carbon Monoxide Poisoning and Compensation—Case citations regarding a truck driver, also a garage worker, who were exposed to high concentration of the gas.—May R. Mayers, Dec. issue, p. 315. E. R. H.

FOOD AND NUTRITION

Is *Salmonella* Food Poisoning Caused by Living Bacilli or by Thermostable Toxic Products?—Eight human volunteers ate custard cultures of *S. enteritidis* or washings from such cultures, the cultures and the washings having been heated or filtered so that supposedly they no longer contained living organisms.

One volunteer swallowed a few living organisms in the heated washings, but was not made ill. Another ate custard that, by mistake, had been heated insufficiently to kill large numbers of the contained organisms, and this subject developed symptoms of severe food poisoning. Nine monkeys were fed with *S. enteritidis* in living suspensions, heat-killed cultures or sterile filtrates. Symptoms of gastroenteritis occurred only when living organisms had been fed. Heated and filtered cultures of enteritidis strains produced no symptoms of food poisoning when living bacilli were not present.

The results provide weighty evidence in favor of living bacilli, rather than thermostable toxic products, being the cause of *Salmonella* food poisoning. The smaller the number of organisms swallowed the longer is the period of incubation. The first sign of illness in both man and monkeys was the development of diarrhea. Cultures of diarrheal stools were practically pure cultures of the swallowed organism, indicating that *S. enteritidis* had supplanted the normal fecal flora. As the symptoms subsided the fecal flora gradually returned to normal.

While enteritidis strains apparently differ in their ability to produce symptoms of food poisoning when fed, it seems probable that when one is working with a single strain, it is the number of living organisms and not their products or the nature of the suspending menstruum that is important.—Elizabeth Verder and Charles Sutton, *J. Infect. Dis.*, 53:262 (Sept.–Oct.), 1933.

The Occurrence and Origin of Lead in Canned Sardines—In routine examination of canned sardines the authors have found metallic impurities—both tin and lead. The tin content is generally 0.1 to 0.2 gr. per lb. The lead content is variable and considering its health aspect the figures submitted are significant.

Out of 596 samples examined, 37 per cent contained from 0 to 5 p.p.m. of lead; 32.6 per cent contained from 6 to 10 p.p.m., and 18.8 per cent contained from 11 to 20 p.p.m. Approximately 9 per cent of the samples showed a range between 20 and 40 p.p.m., and at the extreme range 3 samples contained between 71 and 80, 1 sample between 81 and 90, and 1 sample 150 p.p.m.

The general assumption has been that the lead was derived from solder on the cans. There are three possible sources of contamination: (1) natural lead content of the fish; (2) methods of packing, including the use of solder for sealing, and (3) contamination due to the method of preparation. Raw sardines were found to contain no lead. Samples showing excessive exposed solder compared to those showing little solder, and to those with "sanitary" seals where no lead is present, showed no correlation between the exposed lead or the absence of lead and the amount found in the fish.

There are two methods of preparation—the French method and the Portuguese method, both consisting in cooking the sardines on metal grills. In the French method the cooking is done with hot oil and the Portuguese method by means of a steam-chest at a temperature of 110°C.

Examination of the metal grills showed that they were tin-coated but the coating contained large amounts of lead—in fact, practically representing soft solder. Sardines cooked on old grills showed 44 to 57 p.p.m. of lead,

but fish on the grills newly tinned with block tin showed 7 to 10 p.p.m. It was found also that there is greater contamination from the steam cooking than when cooked in oil.

The authors definitely ascribe the contamination in canned sardines as traceable to the metal grills, although, of course, in some instances there may be a contributory addition where there is exposed solder in the cans. Two methods were used—the chemical method and the photospectrometric method. Figures are appended showing very close check between these two methods when known amounts of lead were added.—L. H. Lampitt and H. S. Rooke, *The Analyst*, 58:733 (Dec.), 1933.

The Comparative Vitamin A Content of Nut-Margarines and Butter—Butter is known to be a rich source of vitamin A but from the reports of most investigators nut-margarines rate low in this vitamin, although nut-margarines containing palm oil have been shown to promote growth in white rats, the palm oil content ranging from 10 to 15 per cent. This investigation concerns a number of uncolored nut-margarines purchased on the open market. After an 8-week feeding period for depleting the body-store of vitamin A in the animals, different samples of nut-margarines were supplied. Animals receiving higher levels of nut-margarines gained some weight during the first 2 or 3 weeks but did not retain it. The highest test at 1 gm. per day was not sufficient to maintain growth during the experimental period of 8 weeks. Better gains were shown on 1/20 as much butter as margarine.

Chemical analysis of nut-margarines showed the moisture variation from 4.34 to 16.69 per cent and the fat from 78.12 to 92.54 per cent. The authors conclude that these commercial nut-margarines are an extremely poor source

of vitamin A and the variation in the fat constituent of the different samples seems to indicate the desirability of establishing standards for this product.—Charles F. Poe and Hazel A. Fehlmann, *J. Dairy Sci.*, 16:559 (Nov.), 1933.

Metabolic Studies of Children with Dental Caries—A group of children ranging from 3 to 20 years of age, averaging about 10 years, was studied with respect to the influence in reference to the variations of diet on dental caries. Determinations of calcium and inorganic phosphorus in the serum show practically no variation in the total amount in 3 groups, totalling 102 observations, the first group with no cavities and no caries, the second group with caries but not active, and the third group with active caries. Concentration of the calcium and phosphorus in the saliva did not differ in these three groups.

A study of the average retention of calcium, phosphorus, and nitrogen showed a correlation of the dental condition. There seems to be a definite relationship between the retention of calcium and phosphorus and the freedom from tooth decay. Calcium and phosphorus retention was also shown to be greater in the case of 7 subjects when the caries were inactive than in the same subjects with active caries. These observations furnish no evidence that dietary deficiency of phosphorus is a definite factor in the incidence of dental caries.

Histological studies show the prevention of caries as dependent upon the deposit of secondary dentin in the tooth and this deposit is determined by the metabolic activity of the individual. The individual utilization of the diets influences the resistance to decay which depends primarily on factors within the tooth. These data indicate that the optimum retentions of calcium and phosphorus are probably higher than

those usually accepted as adequate.—Julian D. Boyd, Charles L. Drain and Genevieve Stearns, *J. Biol. Chem.*, 103:327 (Dec.), 1933.

The Bleaching and Improving of Flour—Reference is made to the report and recommendations of the Departmental Committee of the Ministry of Health of England, published in 1927, and their conclusions to the effect that while not recommending elimination of bleaching agents and improvers, the use of these should be limited in amount. The facts remain that today these substances are more extensively used than ever and it is contended that it would be difficult to ascribe harmfulness in their use.

Different methods of bleaching are described. The essential of bleaching is the reduction of the yellow tint. The question is asked if there is an appreciable amount of vitamin A content contributed by this germ whether or not bleaching should be allowed. The point is raised further that stored flour might be regarded as of lower nutritional value so far as the vitamin A is concerned.

With respect to chemical improvers, to which much objection is registered, the parallelism is drawn between the use of chemical improvers in the food itself and the accepted use of mineral improvers added to the soil in which plant food grows. If the bleaching of flour or improving with chemicals is injurious to health it should be stopped, but no real scientific proof of this is alleged to have so far been produced. Among countries which forbid chemical treatment are France, Belgium, Italy, Greece, South Africa.

If America were to prohibit the addition of chemicals to flour it is held that England probably would follow such practice but it is debated whether this would improve the quality of bread in England and America which is held to be of a higher

standard than that in France where a treatment is forbidden.

In answer to the question whether chemical treatments alter the flavor of bread, the conclusion is reached that bleaching and improving processes did not influence bread flavor one way or the other. It is finally concluded that chemicals are not necessarily harmful in foods since sodium chloride is a well known chemical commonly used and it is recommended that the solution of the problem for the present is to consider every form of treatment or bleaching on its individual merits rather than to promulgate a general approval or disapprobation.—D. W. Kent-Jones, *J. Soc. Chem. Indust. (Chem. & Ind.)*, 52:409 (Nov. 24), 1933.

Bacterial Studies of Defrosted Peas, Spinach, and Lima Beans—Many fruits and vegetables are now preserved by the quick-freezing process. The problem of how frozen vegetables will keep in the home is an important one. Frozen foods may present a distinct public health problem, since knowledge of the bacterial and enzymatic changes that take place during freezing, storage and thawing is still far from complete. The work here reported was undertaken in the hope of contributing something to the knowledge of the bacterial content of defrosted specimens of a few commonly frozen vegetables.

Samples were obtained of fresh peas, spinach and lima beans. One portion of each was frozen by exposure to dry ice while another portion was held in the fresh state. Samples of commercially frozen products were all obtained. Samples of each were then set aside to be held for different lengths of time, one portion of each at 22° C. and one at 6° C. The length of such periods varied from approximately 12 to 72 hours. At the end of the period a quantitative bacterial count was made.

An attempt was made to correlate the types of organisms found in the defrosted samples with the types found in the fresh vegetables. Well isolated colonies were picked from the plates and transferred to agar slants. After incubating for 24 hours at 37° C., preparations from these cultures were stained by the Gram method and were examined for purity and morphology. Transfers were made into various culture media including litmus milk, gelatin, nitrate and tryptophane broth and into fermentation tubes containing dextrose, lactose and sucrose broths.

Fresh spinach, peas and lima beans when stored at 22° C. and 6° C. spoiled after 2 to 4 days, depending upon the initial condition of the product. Similar samples frozen in the laboratory and then defrosted spoiled after 12 to 24 hours at 22° C. and after 36 to 48 hours at 6° C. Commercially frozen samples of the same kinds of vegetables spoiled after 12 hours at 22° C. and after 24 to 36 hours at 6° C. Of the vegetables frozen in the laboratory the spinach spoiled most rapidly. Of the commercially frozen products, the spinach and lima beans spoiled more rapidly than the peas. Whether the more rapid spoilage of the commercially frozen products was due to the use of poor quality vegetables for freezing, to contamination during the process, or to an increase in the numbers of bacteria during storage is not known. The organisms isolated from the fresh vegetables included many micrococci, some bacilli, and a few achromobacter and sarcinae. The organisms isolated from the vegetables frozen in the laboratory included many bacilli, and a few achromobacter and micrococci. From the commercially frozen products were isolated many bacilli, some micrococci, a few achromobacter, and one diplococcus.—Elizabeth B. Brown, *J. Home Econ.*, 25:887 (Dec.), 1933.

CHILD HYGIENE

INFANT MORTALITY

SUMMARY

MORTALITY, MORBIDITY, FATALITY

1. Since the first measures of social hygiene in favor of mother and child were enforced in Germany in 1905 infantile mortality has fallen from 20.5 per cent of living births to 7.9 per cent in 1932.

2. In the past digestive troubles took first place among the causes of death. In the summer months especially, a great number of babies fell victims to summer diarrhea, so that the mortality curve reached a peak known as the *estival point*. In the course of recent years this has given place to the *hibernal point*.

Among the causes of high winter mortality the most important without doubt is the group of acute diseases (influenza) of the air passages, especially *inflammation of the lungs* (bronchopneumonia). A small part only of these pneumonia cases follows upon infantile epidemic diseases, in particular on measles.

Forty per cent of deaths caused by pneumonia in the first year of age take place in the first 3 months of the year (January to March).

MORTALITY IN PRUSSIA (PER 1,000 LIVING BIRTHS)

Year	Pneumonia	Digestive Troubles
1913	10.2	37.6
1930	11.0	10.2

Mortality following on diseases of the alimentary tract has thus very considerably diminished, while that due to pneumonia has to some small extent increased.

While the percentage of deaths due to

digestive troubles fell from 25 per cent in 1913 to 12 per cent in 1930—a 50 per cent reduction—that due to pneumonia rose from 6.8 per cent in 1913 to 13 per cent in 1930—a 50 per cent increase. The mortality of *preschool* age children has also much diminished, but the proportion of deaths *due to pneumonia* has also risen. Indeed this disease touches children particularly during their second and third years, when it is responsible for 28.3 per cent and 17.3 per cent of deaths.

3. Mortality statistics show the important place taken by diseases of the air passages during the first years of life. While we have learned how to fight by preventive measures the high death rate due to disease of the alimentary tract and to reduce it by two-thirds, we do not yet possess similar measures of preventing influenzal diseases. The danger caused by these affections to children in the early years of their life has rather increased than diminished. This has been noted in bad weather years such as 1918 or 1928–1929 (influenza years).

As in the fight against maladies of the alimentary tract the measures to be taken must depend on the clinical and socio-hygienic examination of the conditions that favor the outbreak and the development of the disease.

4. With regard to children we, in Germany, do not possess precise data concerning the *morbidity* of influenza infections nor concerning the *fatality* of pneumonia.

As a result of an inquiry set on foot by the League of Nations in 4 districts of Germany—2 *rural* districts and 2

urban (important centers)—we have established morbidity statistics from which we draw the following conclusions:

(a) Digestive troubles are much more frequent in towns than in the country.

(b) Influenzal diseases are scarcely more frequent in the big towns than in the country.

(c) *Prematurely* born or illegitimate children are not particularly menaced by influenzal diseases.

(d) The frequency of influenzal diseases is higher among rickety children.

(e) The frequency of influenzal diseases rises steadily until the second half of the first year of life has been reached.

Fatality statistics have been prepared on many occasions in Baby Homes and Children's Hospitals. Thus in the "Reichsanstalt zur Bekämpfung der Säuglings- und Kleinkindersterblichkeit," during the period from April 1, 1920, to March 31, 1929, the fatality rate from pneumonia among babies was 42 per cent, and from air passages diseases in general 22 per cent. We note therefore an extremely high death risk among babies suffering from pneumonia. (This is to be explained in great part by the fact that many children are only brought to hospital when in an advanced stage of the disease. Other statistics prepared by the City of Berlin Orphanage show distinctly the relation between immunity and death risk. Thus, while in 1921 and 1922—years when resistance was lowered by epidemics of measles and whooping cough—the death rate rose to 79 per cent. It reached 66 per cent, only, in 1924 and 1925 when general health conditions were better.

CONSTITUTIONAL AND CONDITIONAL FACTORS

5. The beginnings of inflammatory diseases of the upper air passages and of the lungs manifest themselves in two ways: the disease may have a primary character, that is to say, it may appear as an independent influenzal disease;

or it may have a secondary character—it may be a consequence of digestive trouble.

The evolution of an inflammation of the air passages depends, firstly, on constitutional factors, and secondly, on conditional factors.

Among the constitutional factors must be mentioned in the first place the condition of immunity; the less the natural resistance, the graver is the evolution of the disease and the more easily is pneumonia produced. Limited immunity is also a characteristic of an exudative diathesis and of certain cases of neuropathy (vegetative stigmatization).

Among the conditional factors, age, method of feeding, general nutrition, absence or presence of rickets play their part.

Among babies the appearance of pneumonia and its evolution seem to be greatly influenced by social factors. But from the second year of life the appearance of the disease and its evolution seem to be more related to other acute infectious diseases. The influence of social factors on pneumonia in the baby is made clear by the high mortality among illegitimate children who are stricken by this disease; even in the first week of life, their mortality figures are already significant. These figures rise, and continue to rise considerably after the third week, until in the second month of life they reach the triple of those of legitimate children.

6. Statistical research with regard to the moment of the appearance of primary lung diseases caused by an infection, and to the moment of the appearance of maladies following on digestive troubles—secondary diseases—shows that the latter manifest themselves almost exclusively in the first 3 months of life. Thenceforward they become rarer and rarer, disappearing completely in the second half year. Their number, concurrent with the diminu-

tion of digestive troubles, falls to one-third. Primary pneumonias almost never occur during the first 3 months, and become frequent only toward the middle of the first year of life.

ACUTE INFLAMMATION OF THE AIR PASSAGES IN INSTITUTIONS

7. The dangers occurring through contagious diseases, particularly influenza, in whole-time or half-time welfare institutions are well known. According to Pfaundler, the risk of contagion is about 5 times greater for children in creches, day nurseries, and institutions of all kinds than for children living at home. Babies cared for during a long period in an institution contract influenzal diseases about 4 or 5 times during the year. Among hospital babies pneumonia makes its greatest number of victims from December to April, and its smallest from May to October.

The total of hospital pneumonia cases and deaths depends also on other factors; should there be an epidemic of influenza, measles, or whooping cough, or should food be indifferent in quantity or quality, pneumonia figures go up.

PROPHYLAXIS

8. In the present state of our knowl-

edge our chances of preventing influenzal infections, particularly pneumonia, are few. Attempts are being made to prevent pneumonia by *specific prophylaxis* by means of vaccines and serums. The results are as yet not very satisfactory, but it is still possible to make progress in this direction.

For the moment one must try to prevent pneumonia by *general measures*, tending to increased immunity:

(a) By a quantitatively and qualitatively sufficient diet—(for the baby, of course, breast feeding).

(b) By hardening the organism by means of light and air—by artificial sunlight in winter in the countries poor in sunshine.

(c) By the rickets prophylaxis.

(d) By a modern organization of Baby Institutions (Hospitals, Baby Homes, etc.)—sufficient rooms containing only a limited number of beds, facilities for the isolation of the sick and of suspected cases, galleries for air cure, sufficient staff, and a carefully prepared and appropriate diet.—

Professor Dr. F. Rott, Berlin—*Die sozialhygienische Bedeutung der grip-palen Erkrankungen im Säuglingsalter, Association Internationale de Pédiatrie Préventive (Section Médicale de l'Union Internationale de Secours aux Enfants)*, Troisième Conférence, Luxembourg, les 27 et 28 septembre 1933.

PUBLIC HEALTH NURSING*

Write Miss Davis About This—
To meet the demand of laymen who feel a new responsibility because of the economic situation for upholding public health nursing service the N.O.P.H.N. has prepared a series of five study programs for board and committee members.

The first course is a general introductory study of public health nursing in the locality of the group taking the course.

Another course covers the field of public health nursing publicity with full attention given to such media as newspapers, radio, printed material, talks, etc.

An analysis of a volunteer group is also offered. The organization of an active, interested, participating group of volunteers is studied, and methods suggested for utilizing a group of this kind in extending the service of the organization.

The fourth course is an analysis of case material and is devoted to a study of how this material may be applied in illustrating an organization's program. This course is in two series, one for city organizations and one for rural organizations.

The study of the relationship of the board to the professional staff is covered in the fifth course and is devoted to a *Personnel Manual*, recently published by the National Y.W.C.A.

Evelyn K. Davis, Assistant Director of the National Organization for Public Health Nursing, is in charge of the study program.—N.O.P.H.N. *Pub. Health Nurs. News*, 4 (Dec.), 1933.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

Preventing Diphtheria and Scarlet Fever in Nurses—Durand Hospital in Chicago, with a capacity of 60 beds, receives only patients who are ill with infectious diseases (mostly diphtheria and scarlet fever). Nursing is done by student nurse affiliates from other nursing schools in Chicago under trained supervisors.

Every effort is made to protect the health of these nurses. Nose and throat cultures are made regularly each week; a high degree of cleanliness of patients and surroundings is maintained; their technic and procedures are rigidly supervised.

Careful records have been kept of the incidence of scarlet fever and diphtheria in the nurses while on duty. All are given the Schick test and the positives are immunized to a negative Schick before entering on duty. Not a case of diphtheria has developed among the nurses since December, 1927.

The Dick test is also given all nurses and a preventive injection of toxin is given all susceptibles. Not a single case of scarlet fever has developed among them since December, 1927, either.

The writers repeat the statement given in a former report: "By means of Schick and Dick tests followed, when necessary, with active immunization, nurses can be selected who are practically free from the danger of diphtheria and scarlet fever."—Ludwig Heketoen, M.D. and Charlotte Johnson, R.N., *J.A.M.A.* 102, 1:41 (Jan. 6), 1934.

More About C. W. A. Nursing—A Child Health Recovery program has been launched in California with 50 C.W.A. nurses, formerly unemployed,

at work, locating undernourished children. Later plans will be made to try to overcome the malnutrition, where it exists, and prevent further progress through dietary measures and, where necessary, corrective medical procedures. There will be a general supervisor of the nursing program with 5 district supervisors to work more closely with the staff nurses.—*Weekly Bull.*, California State Dept. of Public Health XII, 51:20 (Jan.), 1934.

The Illinois State Nurses' Association through its Placement Service has approved and assigned 600 C.W.S. nurses for service in public health in Illinois.—*Health Broadcaster* V, IX (Jan.), 1934.

Two Members of Our Section Make Changes—Katherine Faville, who has been head of the Department of Nursing, College of Liberal Arts, Colleges of the City of Detroit, on February 1 became associated with Marion G. Howell, Director of the Course in Public Health Nursing in the School of Applied Social Sciences, in Western Reserve University, Cleveland, Ohio.

Ruth E. Mettinger of Sanford, Fla., left her duties as Red Cross Nursing Field Representative for North and South Carolina, Louisiana, Mississippi, Alabama, Georgia, and Florida, January 29 to head up the Bureau of Public Health Nursing in the Florida State Board of Health.

On to Washington!—Many nurses and lay members of public health nursing boards are making plans to attend the Biennial Nurses' Convention in

Washington, D. C., April 23 to 27, inclusive. National Organization for Public Health Nursing headquarters will be at the Hotel Washington.

N.O.P.H.N. general session topics will be: New Developments in Public Health and Social Work; Public Health Nursing To-day; Maternal and Child Health, Communicable Disease, Nutrition, and Mental Health; The Changing Order and Community Planning.

There will be round tables according to population groupings and for school and industrial nurses. One session is left free for discussion of whatever public health nursing problems are most pressing in April.

There will be luncheons galore for: I.V.S. Advisory Council; Board and Committee Members; field nurses; Chairmen of Public Health Nursing Sections of S.N.A.'s. No nurse needs to be left out in the cold. She will belong somewhere every minute of the time.

The American Nurses' Association and National League of Nursing Education programs will be in an early issue of the *American Journal of Nursing*. The programs of the joint sessions will appear in the February, 1934, *Public Health Nursing*.

The American Nurses Association with over 120,000 members is the largest professional organization for women in the world and its convention in conjunction with that of the N.L.N.E. and the N.O.P.H.N. means a great deal to American nurses.—*N.O.P.H.N. Listening in*, III, 1 (Jan.), 1934.

EDUCATION AND PUBLICITY*

It Was "Almost 100 Per Cent News"—From time to time this department has urged the publicity value of studies in public health, even beyond the cities where they are made. Some are more widely usable than others, but the *News-Letter* of the Commonwealth Fund, New York City, reports on one of the extra successful reports:

Late in November, the Fund published *Maternal Mortality in New York City*, the report of a study made by the New York Academy of Medicine. This was greeted by the most extensive publicity ever accorded to any Fund publication. A summary prepared and issued by the Academy of Medicine led 310 newspapers in 39 states to devote 2,355 column inches to the report, and the clippings are still coming in. In New York City both the *Times* and *Herald-Tribune* printed the summary practically in full, starting on the front page. The *Times* and the *World Telegram*, and several papers outside of New York, discussed it editorially, and several weekly magazines, including the *Literary Digest*, *Colliers*, and *Time*, dwelt on the importance of the study. The *Journal of the American Medical Association* published the summary in full.

So extensive was the newspaper attention to the report that an article in *Editor and Publisher* made it the subject of discussion, analyzing, "as a test of intelligent news handling," the use made of "this almost 100 per cent news item."

Dr. Hooker, director of the study, knows of no less than 15 communities, including Buffalo, Philadelphia, Pittsburgh, Boston, Cincinnati, Atlanta, New Orleans, St. Louis, and Oakland, California, which have undertaken or are now beginning studies patterned after and stimulated by this project.

Looking Backwards to "How Difficult Is Truth"—Last month we quoted a statement about the certainty of recovery from diphtheria when a

case received "sufficient serum on the first day of illness," following this with a quotation from another source questioning the first statement.

The follow-up comes in a letter:

Although at first I felt you were a little rough on us, I do not now feel so after hearing from Dr. Park and, just by accident, from Dr. _____.

I doubt if anything in medicine is quite one hundred per cent. Probably Ivory soap has the percentage more clearly worked out.

I do not believe you intend the apparent inference that the statement was just an overnight haphazard somewhat random one not based on adequate consideration and study. As a matter of fact, back of it goes more than ten years of personal investigation of diphtheria deaths from the point of view of date of onset and the date of first antitoxin.

The writer of the above letter received the following from an authoritative source:

Of course I have serious objections to saying that anything invariably results from any given set of known causes. I dare say the day will come when the sun will not rise, if you can call that a day.

I do not know that Mr. Routzahn's statement is any more true than yours. I do not believe that anyone has figures based upon unequivocal data which would enable them to say what the percentage of deaths is. Obviously if one wanted to quibble he could say that no dose which failed to cure was sufficient.

Health education offers many such perplexing situations.

The Twentieth National Negro Health Week—As has become customary, the U. S. Public Health Service is sending out samples of materials for use in organizing local observances April 1-8, 1934. The official announcement says:

National Negro Health Week was initiated in 1915 by the late Booker T. Washington.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 139 East 22d St., New York, N. Y.

It was not a birth, but rather an adoption. The Negro Organization Society of Virginia, with headquarters at Hampton Institute where then resided Maj. R. R. Moton, commandant, friend of Booker T. Washington, is the real father of Health Week. Dr. Washington sensed the capacity of this movement and appreciated its possibilities, and thus became the All-American champion of Negro health.

The announcement briefly reviews the development up to 1934 when 45 national or regional organizations, white or colored, unite in the call.

The program for the Week includes: Sunday, Mobilization Day; Monday, Home Health Day; Tuesday, Community Sanitation Day; Wednesday, Special Campaign Day; Thursday, Adults' Health Day; Friday, School Health Day; Saturday, General Clean-Up Day; Sunday, Report and Follow-Up Day.

Limited quantities of material will be supplied without cost, samples being sent to health agencies upon request. A dramatization of "The Daily Half Dozen" will be sent upon request. Address: National Negro Health Week, U. S. Public Health Service, Washington, D. C.

Quantity orders should be sent to Superintendent of Documents, Washington, D. C., for the following: poster, 100 for \$1.80; bulletin (with plans), 100 for \$1.40; leaflets for schools, 100 for 30 cents.

A Newspaper Desk Book—Most newspapers develop style or rules in capitalization, punctuation, and so on. In many cases this style is printed on a sheet or a pamphlet. In other cases it may be but a typewritten sheet posted in the city room. Other newspapers merely pass on the style from editor to reporters.

The *Iowa Newspaper Desk Book* is a compilation of the School of Journalism, suggested for use by Iowa newspapers, which says:

A newspaper usually develops a set of individual usages due to office necessities or the opinions, habits and whims of executives. Such development of the individuality of a paper is to be encouraged so long as it does not lead to unjustifiable and freakish eccentricity. . . .

There are many controverted matters in modern punctuation, capitalization and diction. This style book has had to record arbitrary decisions on all disputed points. Some of these decisions have been arrived at only after laborious study of authorities—especially that authority represented by the consensus of usage of the better newspapers.

Newspaper capitalization and punctuation is sharply divided from that of books. The "down style" of typography has won its way with the newspapers, and the end is not yet. The psychologists have shown us that lowercase letters read much more easily than capitals, and linotype operators have developed great increases in speed from the limitation of "caps." Likewise, it has been found that much of the nicely logical but "fussy" punctuation developed by the more pedantic is not necessary to clearness, and as a result the modern newspaper gets along very well with about half the volume of points used in book composition.

Among the chapters are those on reporting (of special value to those who write on health topics for newspaper use), capitalization, punctuation, abbreviation, figures, titles, spelling and division of words.

The health workers may well use this as a guide in writing copy, making note of standardized variations observed in the local newspapers. Issued by University of Iowa, Iowa City, Ia. 1933. 54 pages. 10 cents.

Public Health Education Section at Pasadena—The Section Council met as a program committee in New York, Feb. 3, with Chairman Shepard of San Francisco, and Secretary Connolly of Detroit among those present. An attractive and useful program was planned. It was decided to conduct a Health Education Institute which should be devoted to school health education.

"Carrying the Message to the People"—This is the happy title of a chapter in *A City Set on a Hill*, by C.-E. A. Winslow. In that review of the significance of the Syracuse Health Demonstration the twelfth chapter takes up the necessity for the health services having behind them "an aroused and intelligent body of public opinion" for "the people as a whole must comprehend the needs for such services and the value of such services" if those services are to be supported and if they are to be well utilized by the people.

Here Prof. Winslow outlines concisely the relationship of health education to the health program as a whole, plus three essential characteristics of satisfactory health education:

... it is now recognized that an organized program of popular health instruction must form a vital element in the general scheme of community health promotion. Such a program should be planned to bring to the people of the community the increasing knowledge of the principles of medical and sanitary science which they need to apply in their daily living, as individuals and as a group, for the attainment of maximum health and efficiency. It should utilize all the resources now available for disseminating information: the press, the platform, the radio, the cinema, the exhibit, the printed pamphlet, and the like. In so doing, it must keep three conditions always in view. It must bring to the people only what is established on a sound scientific basis. It must present its facts with the most effective technic, as to selection of content and form, so as to make the essential facts clear and to arouse an effective desire to apply them. And, finally, the program must be so planned as to emphasize those things which are vitally important and to do so at the times and under the conditions where application of the principles in question can most easily and effectively be made.

In the light of the above the most significant statement in the chapter is the following, which we put into italics that none may overlook it:

To attain such objectives as these clearly requires definite and specific leadership by persons with special train-

ing in the technic of presentation. If the modern health program is to bear its fullest fruit, the Health Department must have a special division of popular health instruction under the direction of a trained specialist in this field.

We count upon this chapter as a whole being widely read by public health workers who will so generally wish to study the Syracuse experiment through the eyes of Prof. Winslow. Briefly, the chapter takes up the need for organized health instruction; development of popular health instruction in Syracuse; the Bureau of Health Education of the Health Department; the Onondaga Health Association; community planning; appraisal and costs of popular health instruction.

There are frequent references to a "program of health education" but there is little light on what that program was, on what it was based, or how it was arrived at. Is it not natural for the reader to make the obvious deduction that the program is made up largely of the materials and activities which occupy much of the chapter?

A program or a plan for health education, as we see it, is not the planning of the details of a particular project or event. Rather we are thinking of a plan or program for a year or other extended period. It is the selection of the objectives and the chief audiences and mediums mapped out in relation to the needs of the community and the resources of the health agency, or the group of health agencies.

Unhappily, the appraisal form does not call for a program or plan, and none of the health survey reports, as we have seen them, record the lack of a program, or propose one for the future. Hence the disappointment that in *A City Set on a Hill* there is not described a broad, solid base of program planning for the admirable health education activities presented in this chapter.

A City Set on a Hill is published by

Doubleday, Doran and Co., Garden City, N. Y. 382 pages. \$3. Order from A.P.H.A. Book Service.

"Health Exhibitions" — by J. Mackintosh (*Mother and Child*, 5 Tavistock Square, London, W. C. 1. July, 1933. 9d. a copy), mentions that

In the history of public health during the present century, the contribution of the health exhibit has been of incalculable value. Long before the War small exhibits had been shown from time to time in connection with courses of lectures on hygiene.

Mr. Mackintosh traces the holding of the successive large-scale exhibitions in connection with National Baby Week, and the development of the exhibition idea by the National Council of Maternity and Child Welfare.

The Council maintains a permanent exhibition at Carnegie House, 117, Piccadilly, London, W. 1., illustrated in connection with the article, to be noted on the itineraries of health workers from other countries. The Council is a continuous source from which many traveling exhibits are sent throughout the year.

Local Clinics on Amateur Movies—Health councils have received from Social Work Publicity Council a suggested plan for demonstration and clinic sessions on the use of amateur motion pictures. A copy of the plan will be sent to any one interested in the use of home-made pictures by health and welfare groups.

The Council has issued a "List of Amateur Motion Pictures" which may be drawn upon in planning a local demonstration. Send 6 cents to Social Work Publicity Council, 130 East 22d St., New York, N. Y.

From these memoranda we quote the following on "What Is An Amateur Movie":

The term is elastic for the purposes of this memorandum. It covers any picture not

wholly or primarily a professional production.

The photography may be done by a staff member—by a board or committee member—by an amateur movie volunteer—even by a professional photographer (as has been done in a few cases).

Common to all amateur pictures is the 16 mm. non-inflammable film, usable in projectors without a booth.

The amateur picture is not bound by conventions of theatrical production, nor hampered by visions of the theatrical audience. As a rule it is intended for a more intimate presentation, although modern 16 mm. projectors permit successful screenings up to 500 in the audience. Drama or plot is not essential, but effective continuity is an important element in the successful picture. (Valuable assistance in planning the continuity may be secured from Amateur Cinema League, 105 West 40th St., New York, N. Y.) Advance planning before production is of paramount importance in achieving effectiveness in an amateur picture. The available equipment makes poor photography inexcusable.

Getting Books Read—Probably we have done too little in promoting the use of our public health journals. Equally important, and probably more difficult to carry through, is the wider use of supplementary sources for health workers, physicians, and other groups.

The National Tuberculosis Association

is experimenting with the use of a package library for physicians. The library is designed especially for use at medical meetings, selected clinics where physicians have time to look over books, at medical libraries and so forth. Arrangements may be made with the National Tuberculosis Association for the loan of the library. There is no charge for the books but the borrower must pay the transportation charges both ways. The package weighs approximately 20 pounds.

The Brooklyn Tuberculosis and Health Association, 293 Schermerhorn St., has assembled a "Minimum Tuberculosis Library for Physicians" which is thus described:

This abbreviated shelf of books covering all phases of Tuberculosis represents what may be called a minimum library that every physician, whether in general or specialized practice, should either own or to which he should have easy access.

Health Education in Indiana—

Health education work in Indiana is now being carried on under the supervision of the Indiana University School of Medicine and the state and local medical associations. In this set-up the Bureau of Health Education in the Division of Public Health acts as a contact medium between the lay public and the medical profession, helps plan health programs and campaigns, secures speakers, provides health films, literature, exhibits, etc. This service and material is furnished without cost.

To receive the coöperation of the Bureau, any group wishing to put on a health program must first secure the approval of the local medical society through its secretary. This approval is absolutely necessary.

The next step is to inform the director of the Bureau, giving him ample time, as to the date, hour and place of the proposed meeting and the subject of the talk, films, or exhibit desired. The Bureau will then make the necessary arrangements. If the local medical society prefers, a speaker from outside the community may be secured, but as a rule local physicians are ready and willing to fill these engagements.—

Echoes, State Bureau of Public Health Nursing, Indianapolis.

A Compliment from North Carolina—A marked copy of *Health Bulletin*, North Carolina State Board of Health, comes to us carrying a two-thirds of a page quotation from this department of the *Journal*.

DEPRESSION

The references under this heading may supply background material for writers or speakers. Some of the references may be useful to officials or to relief and family welfare agencies—if passed on to them.

"Economic Aspects of Present-Day Health Problems," by W. W. McFarland, M.D., *Pennsylvania's Health*, State Dept. of Health, Harrisburg, Pa. Nov.-Dec., 1933. Taxpayer's viewpoint plus necessity of maintaining standards.

"Sickness Among the 'Depression Poor,'" by Perrott and Collins. *American Journal of Public Health*. Feb., 1934.

"Sickness and the Depression," by Perrott and Collins; and "Diets of Low-Income Families in Cleveland, Detroit and Syracuse," by Wiehl. *Quarterly, Milbank Memorial Fund*, 40 Wall St., New York, N. Y., Jan., 1934. 25 cents. The first is a "preliminary report upon a survey of wage-earning families in Baltimore, Cleveland, and Syracuse.

"Youth Never Comes Again," by Clinch Calkins, is for those who are concerned about the excessive free time of present-day young people, and those who want to do something about it. There is the definite suggestion that "health and hygiene groups (public and private)." are among those interested in a program of adult education. 71 pages. 25 cents. Committee on Unemployed Youth, 450 7th Ave., New York, N. Y.

"Idleness and the Health of a Neighborhood" is one of those rare studies for which a previous study made in 1922 provided "a background of fairly normal conditions against which the disruption of health and economic life during the depression years stands out sharply." This study was made by G. H. Berry, and published by New York Association for Improving the Conditions of the Poor, 105 East 22d St., New York, N. Y. 102 pages. Diagrams and tables. \$1.00.

"The Importance of Milk in Relief Diets" is a 3-page review of recent discussion, with a half dozen reading references. National Dairy Council, Chicago. Free.

BULLETINS

"The Handicapped" is the general theme of the Oct.-Dec., 1933, issue of *Commonwealth*, Massachusetts Dept. of Public Health, Boston. 111 pages, to which is added a 6-page index for the 4 issues of the year.

Health News, New York State Dept. of Health, Albany, N. Y., appears in

a brand new dress. Get a copy and see it for yourself.

A special milk number of *Canadian Public Health Journal*, published by Canadian Public Health Assn., devoted 52 pages to a variety of topics from the farm and the home, and the problems and procedures along the way to safe and wise use of milk. Jan., 1934. 105 Bond St., Toronto, Ontario. Reprints, 35 cents.

EDUCATION AND REFERENCE

Here are listed publications for background in writing and speaking, for intensive use with especially selected individuals, or for more general use in the community.

Another booklet issued by Cancer Control Committee of Dept. of Health, New Haven, Conn., carries on its front cover the rugged heights of cancer mortality expressed in a solid diagram, this time in purple. The illustration "bleeds" over the left, right, and lower edges of the page. "Cancer," appears as a title set in the upper white space section.

"Asphyxial Death" is a one-page copy of an editorial comment in the *Journal* of the American Medical Assn., reproduced on a cover-page of the *Journal*. Illustrates use of the off-set process when one wishes to tie-up the authoritative journal with a clipping. Society for the Prevention of Asphyxial Death, 2 East 103d St., New York, N. Y. Send 3 cents postage.

"Cancer—A Challenge," by Shields Warren. A. M. A., 535 North Dearborn St., Chicago. 9 pages. 10 cents.

"For Good Health," a poster, mostly a well lettered placard. A simple food selection guide. Metropolitan Life Insurance Co., New York and Ottawa. Free.

"How to Gain Weight: It Is Important for Some to Know," by Laura A. Miller. A. M. A., 535 Dearborn St., Chicago, Ill. 9 pages. 5 cents.

"Maternal Deaths," by Children's Bureau, Washington, D. C. "Brief report of a study made in 15 states." Superintendent of Documents, Washington, D. C. 5 cents.

"The Partial Conquest of Heart Disease," by D. B. Armstrong, M.D. Metropolitan Life Insurance Co., New York, N. Y. Free. Reprint from *American Medicine*.

"The Practice of Preventive Medicine by the Private Practitioner," by Iago Galdston, M.D., New York Academy of Medicine, 2 East 103d St., New York, N. Y. 15 pages. 10 cents. Reprint from *Health Examiner*. Includes an interpretation of the periodic health examination.

"Tuberculosis—A Family Disease: Social Aspects," by Edward Hochhauser, Committee for Care of Jewish Tuberculous, 71 West 47th St., New York, N. Y. Reprint from *Transactions of National Tuberculosis Assn.*, 1933. "An increasing percentage of our tuberculous patients discharged from hospitals and sanatoria can be rehabilitated through greater interest in the family method of treating the patient." Send 3 cents postage to the author.

"What Builds Babies?" Revised, 1933. Children's Bureau, Washington, D. C. Single copies free. 8 pages. "The mother's diet in the pregnant and nursing periods."

HONORABLE MENTION

To Department of Public Health, Union of South Africa: for full table of contents in annual report.

To State Board of Health of Maryland: for Annual Report with both table of contents and index. Quite detailed index taking 19 pages of the 235-page report; with references to health education in Letter of Transmittal, and reports of Bureau of Vital Statistics, Bureau of Child Hygiene, and Division of Oral Hygiene.

TO DO OR TO USE

"Friendly Messengers Carrying Lessons of Health," by Mary P. Connolly. How the Detroit Health Dept. and Detroit Chapter of the Red Cross reach the local Negro population. *Red Cross Courier*, Washington, D. C. Dec., 1933. 20 cents.

"Health Recovery Campaign," in "Public Health Administration" section, *American Journal of Public Health*. Feb., 1934. With illustrations of materials for use in the 1934 Early Diagnosis Campaign.

In "Health Examinations," by M. A. Lundwall (*Womans Press*, 600 Lexington Ave., New York, N. Y. Feb., 1934. 20 cents), is a reminder of educational use to be made of record data:

When a comparative study is made of the 3 years' examinations some interesting conclusions may be announced, such as the effect of economic stress on general health; the influence health teaching has had in the change of health habits. At present, the health and physical education program must be worked closely together if the individual is to attain that joy of living which comes from practising health habits intelligently.

Snapshots at night are now possible with a new supersensitive film, taken with the aid of two or three of the photoflood bulbs. The film has three times the speed of ordinary film under ordinary light.

MOTION PICTURES

For advance information about dates for "Damaged Lives" at your local motion picture house address: American Social Hygiene Assn., 450 7th Ave., New York, N. Y.

A new folder "Facts—Results" tells in striking fashion about the reception given to "Man Against Microbe," the motion picture of Metropolitan Life Insurance Co., New York and Ottawa. *Free*.

"This business of continuity" explains the significance of "continuity" in the production of motion pictures.

"Clipper explodes" shows how to handle negative to produce continuity. "Weaving a magic carpet" discusses travel pictures, but much of it applies to pictures of health camps, classes and institutions. "The formula needs no magic—only careful planning." All in *Movie Makers*, 105 W. 40th St., New York, N. Y. Oct., 1933. 25 cents.

RADIO

John McCormack, in an interview on broadcasting, in *New York Times*, Dec. 3, 1933, said:

The English . . . seem to have discovered the knack of making abstruse subjects clear, interesting and entertaining. American broadcasters should concentrate on more speakers who devote their talents to presenting interesting topics in a popular style.

"The Drug and Beauty Racket." *Education by Radio*, National Committee on Education by Radio, 1201 16th St., N. W., Washington, D. C. Racketeering via Radio. *Free*.

Health by Radio is a 155-page, paper-bound book, reporting "the sixth hundred of a series of health talks broadcast every Friday night by the New York State Dept. of Health from Station WGY." From the introduction:

Over 10 years have passed since the Division of Public Health Education of the State Department of Health, began broadcasting health information from Station WGY, Schenectady, through the courtesy of the General Electric Company.

There is no way of estimating the amount of human suffering which has thus been prevented or alleviated. The advice and suggestions given by the authors of these talks must have resulted, however, in a far better general understanding of basic facts relating to health and disease.

Individual copies of any of the broadcasts contained in this booklet can be obtained by writing to the Division of Public Health Education, State Department of Health, Albany, N. Y.

In June, 1933, *Hygeia* carried a devastating article on "The Radio Gymnasium Class," by Alfred C.

Boand, 'self-confessed leader of radio classes. After a thorough deflation the author proceeded to reflate and stabilize the radio gymnasium class on the basis of certain definite specifications. The article makes good reading for those who like *American Mercury*. In Oct., 1933, *Hygeia* published an answer from Dr. Jesse Feiring Williams of Teachers College, an interpretation of modern physical education vs. the radio class.

SOCIAL HYGIENE

"Attitudes and Practices of Parents in Sex Education of Children," by M. S. Dillon. *Journal of Home Economics*, Baltimore, Md. Dec., 1933. 30 cents. In this study ". . . the second outstanding finding, and probably the most important, was the amazing inconsistency shown by the parents between their opinions, so enthusiastically and sincerely expressed, and their practices."

"Fight Venereal Diseases with Knowledge." City Health Dept., Baltimore, Md. 8 pages; heavy paper; pictorial cover. The needed knowledge about the three venereal diseases.

"Social Hygiene Exhibit Screen." American Social Hygiene Assn., 450 7th Ave., New York, N. Y. Free. A small folder illustrating and describing a 3-wing display screen, with 19 samples of publications. Screen is sold, or loaned for transportation cost.

"The Wonderful Story of Life," New York State Dept. of Health, Albany, N. Y. 24 pages. Parents' talks to be read or told to young children.

From "Social Aspects of the Venereal Disease Problem in Canada," by F. S. Parney, M.D. *National Health Review*, Ottawa, Ont., we glean the following:

In the war against venereal disease others than the psychologist have parts to play. The physiologist must prepare for the guidance of parents and the laity in general, a plain, simple, but comprehensive statement of scientific facts regarding the physiology of sex, just as he has done in the past with re-

gard to the physiology of digestion, assimilation and excretion of food materials.

The educationist, either through the department of health or voluntary health and mental hygiene organizations, must get this information over to the public in such a matter-of-fact way that it will become part and parcel of the individual's idea not only of personal hygiene but also of his normal social adjustment.

WANTED!

We have been asked for information about adult or popular health education programs.

Please send copies of office memoranda, reports, or other material to editor of this department.

Have you a program of adult or popular health education for your city, county or state?

Have you an article, a convention paper, or other material discussing such programs?

REPORTS

The "Annual Report" of American National Red Cross (Washington, D. C.) for year ending June 30, 1933, as usual includes a helpful device. At the head of many of the service chapters is an explanatory paragraph. For example: under "Public Health Nursing and Home Hygiene" appears the following:

The Public Health Nursing Service spreads knowledge of healthful living and coöperates with health authorities and the medical profession in checking the spread of disease. Home Hygiene and Care of the Sick gives practical instruction in infant and child care and in home care of the sick and develops correct attitudes toward health and disease.

From the Annual Report of Royal New Zealand Society for the Health of Women and Children:

The Society was started as a League for mutual helpfulness and mutual education, with a full recognition of the fact that, so far as motherhood and babyhood were concerned, there was as much need for practical reform and "going to school" on the part of the cultured and well-to-do as there was on the part of the so-called "poor and ignorant."

MAGAZINE ARTICLES

"I Read That in a Magazine" introduced the following:

This publicity slogan is the basis of our policy of reporting what current magazines are saying about social problems and social work. What your magazine reading public is being told builds up a degree of acceptance or resistance to your own publicity. Even though the articles may not bear directly on your own work, they help create a frame of mind in which social work information takes a more important place. Some of these articles may be overlooked by your public unless you call attention to them. There is another reason, or we might call it a hope, connected with our reviews—that now and then some of our members will write at least as much as a postal card of appreciation to the editors, when their articles interpret social work well.—

News Bulletin, Social Work Publicity Council, 130 East 22d St., New York.

So say we for this section of "Education and Publicity." Many of the articles here listed during the year contain quotable material for speakers and for other uses. The articles also suggest angles or slants of approaches for making old stuff fresh and interesting.

"A Diet Lesson from the Arctic," by K. Glover. *Herald-Tribune Magazine*, New York, N. Y. Jan. 28, 1934. Pre-packed daily balanced rations.

"A New Approach to Sex Education," by C. Pilpel. *Delineator*, New York, N. Y. Oct., 1933. 10 cents. "Delineator has paved the way with fearless discussions on this subject."

"Why Die Before Your Time?" by H. S. Williams, M.D. *Collier's*. Jan. 13, 1934. "It's a silly thing to do . . . but most people are, or will be guilty."

SAFETY

"An Auto Sherlock Holmes," by F. M. Kreml. New York *Herald Tribune Sunday Magazine*. Dec. 31, 1933. How the Evanston police catch and convict traffic law violators.

"Blind Drivers with Good Eyes," by

Dr. C. E. Pollard. *Kiwanis Magazine*, 520 N. Michigan Ave., Chicago, Ill. Dec., 1933. 15 cents. Mental factors and eye habits which produce car accidents. Something to do something about.

"Industrial Hygiene and Safety," Metropolitan Life Insurance Co., New York, and Ottawa, Ontario, briefly defines "industrial hygiene" and "industrial safety," and then explains the publications and other services offered by the Metropolitan. 24 pages. Free.

SCHOOLS AND CHILDREN

The entire Oct. 15, 1933, issue of *Health Briefs* is devoted to the "Blue Ribbon Program" in the schools of Tennessee, promoted by the State Dept. of Public Health, Nashville.

Any child is eligible to receive a Blue Ribbon when evidence is shown that he (a) is making satisfactory progress in his studies; (b) is amenable to the ordinary requirements of school discipline; (c) is reasonably cooperative in the practice of health habits; (d) is free of remediable physical defects and meets certain immunity standards. Immunization standards include protection against typhoid fever, diphtheria and smallpox.

"Health Instruction in Grades IX-XII," by J. F. Rogers, Office of Education, Washington, D. C. Sold by Supt. of Documents, Washington, D. C. 5 cents. From "Theory and practice" to "College credit." 22 pages.

"Teaching Health in School Cafeterias: Baltimore's Poster Program." *Trained Nurse and Hospital Review*, 468 4th Ave., New York, N. Y. Oct., 1933. 35 cents. Illustrated description of visual material for stimulating wise food selection.

"Your Child and the School" is a series of 10 newspaper articles by Dr. Allen G. Ireland, director of physical and health education, N. J. State Dept. of Public Instruction. Mats supplied free by Health News Service, 22 East 40th St., New York, N. Y.

BOOKS AND REPORTS

Report to the United States Government on Tuberculosis with Some Therapeutic and Prophylactic Suggestions—*By S. Adolphus Knopf, M.D. Revised and Enlarged Report submitted to the State Department, War Department and War Veterans Bureau as Government Delegate to the International Union Against Tuberculosis Held at the Hague, Sept. 6-9, 1932. New York: The National Tuberculosis Assn., 1933. 59 pp. Price, \$1.15.*

Dr. Knopf's lifelong interest in tuberculosis, his command of languages, his wide training and familiarity with European as well as American conditions, make him singularly fitted for the task on which he here makes a report. Of particular interest is his observation of the use of sanocrysin, but in view of the contradictory evidence reported by Dr. Knopf, we still remain unconvinced. We commend his final paragraph in answer to Professor Bernard, who claimed recovery or notable improvement in some 50 per cent of the cases treated with sanocrysin, in which he points out that by hygienic and dietetic methods, clinical recovery or notable improvement in 50 per cent or more cases is obtained.

The second chapter is devoted to the after-care of tuberculous subjects. England has its notable tuberculosis villages, such as Preston Hall and Papworth. Germany has tried to found establishments, but up to the time of this report, there were no institutions for tuberculous war veterans. France has created a Sanitary City, which Dr. Knopf thinks will do much good. It is evident that the United States is doing better by its veterans than any other

country, as there are now 14 hospitals for the care of tuberculous veterans, as well as other public facilities, in addition to which we have a number of private and state institutions.

The author gives a full description of his respiratory therapy or diaphragmatic respiration, which has attracted much attention. Preventive inoculation with BCG is considered favorably. The last chapters are largely given up to the prevention of tuberculosis in children by breathing exercises, outdoor life, etc.

The book is abundantly and beautifully illustrated, the frontispiece being a photograph of the Queen Mother of the Netherlands, who was Patroness of the Conference at the Hague. There are photographs of the institutions in England and elsewhere, and a full series showing respiratory exercises.

The report can be recommended as a record of the observations of an interesting trip emphasized by important conferences and visits to war veterans hospitals made by an enthusiastic and competent specialist in tuberculosis.

MAZÏCK P. RAVENEL

The Human Problems of an Industrial Civilization—*By Elton Mayo. New York: Macmillan, 1933. 194 pp. Price, \$2.00.*

This volume proceeds at once and without introduction to its subject matter, comprising eight chapters: I. Fatigue, II. What is Monotony? III. The Hawthorne Experiment, IV. Development of the Western Electric Inquiry, V. The Meaning of "Morale," VI. The Reaction of Industry upon the Social Order, VII. Theories of Government and the Social Order, VIII. The

Problem of the Administrator—especially the new administrator.

Excerpting much literature as a *basis argumenti*, particularly in the earlier chapters (the author index lists several citations from most of its 65 sources), the author develops his own special field in the later chapters.

There is a tendency to lengthy quotations, repetition, and verbosity, and some may wish that a summary had been provided for each chapter, but the concluding chapter is of summarizing type. Fault may also be found in omitting references to other works of the same tenor such as Frankel and Fleischer's *Human Factor in Industry*, and the findings and efforts of the Life Extension Institute and its former medical director, Dr. Eugene L. Fisk, likewise the annual reports of the Committee on Fatigue of the Industrial Hygiene Section of the American Public Health Association. However, the literature cited is widely selected and authoritative.

The practical applications made at the Hawthorne Plant of the Western Electric Company make very instructive reading; after all, there is always the individuality, the psychology and the group response of the human being to be considered.

We think the author missed it in his implied prophecy (p. 184) wherein he discusses the abandonment of the gold standard in England with so little local (English) excitement, and asks whether such a step in the United States would have so little effect, or "cause no visible tremor in the social life of the country?" The remark was made just prior to our own abandonment of the gold standard (and whatever "tremor" this did cause).

The book represents the author's contributions to the Lowell Lectures given in 1933, and embodies some conceptions of the methods and findings of several groups of workers at Harvard

University in their industrial investigations. The concluding dogma is, collaboration based upon the coherent unity of biochemical, medical, industrial, and anthropological factors in the perfection of our industrial civilization—certainly an ideal concept and masterfully handled in the present work. The book will interest all who have to do with employee problems.

EMERY R. HAYHURST

Red Medicine: Socialized Health in Soviet Russia—By Sir Arthur Newsholme, K.C.B., M.D., and John Adams Kingsbury, LL.D. New York: Doubleday, Doran, 1933. 324 pp. Price, \$2.50.

The descriptive phrase, "Sketch of Medical and Public Health Administration in Soviet Russia," which is found in the Introduction, admirably characterizes this very readable book.

Sir Arthur Newsholme's earlier report for the Milbank Memorial Fund, *International Studies on the Relation Between the Private and Official Practice of Medicine, with Special Reference to the Prevention of Disease*, did not include a study of Russia. It was later decided that an investigation of Russian medico-social problems would be of benefit, and this book represents the result of an extensive, though brief, trip through Russia for such purposes. Adequate introductions, special conferences, with a background of reading and direct inquiry afforded the authors an unusual opportunity for obtaining accurate information.

Approximately the first half of the book is taken up with a diary-like outline of the trip which led from Moscow and Leningrad through Georgia, the Crimea, the North Caucasus, the Black Sea area, and the Ukraine, and general information regarding Russia's early government, the industrial and agricultural situation, and civil and home life. All this is included in order to give

the reader a proper appreciation of the latter half of the book which records a statistical and critical survey of medical conditions. This section includes chapters on such subjects as care of children and mothers, abortions, social insurance, public health work, medical training, care of the sick, control of tuberculosis and venereal diseases.

Every doctor in Soviet Russia is a state official with regulated salary; every individual a state responsibility. A doctor may choose his location for practise, may practise privately after his daily duties to the state are finished, and he may specialize after qualifying by special examination. While the standards of medical education are lower than in this country, they are improving. More women than men are now practising, and there is no sex discrimination.

The individual may choose his doctor within his district. If he is sick and unable to leave his home he is visited by a doctor. Whenever it is possible he is made to go to a neighborhood dispensary and is then sent to a central polyclinic or hospital. In most cases there is no fee. As an individual, a woman may decide the question regarding abortions after the first pregnancy; the state regulates the procedure. Prenatal and postnatal care are supplied, and state care of children is free to the working mother.

There are many rest and convalescent homes and sanatoria, chiefly for tuberculous patients. Adequate provision is made for the control and treatment of venereal diseases.

The good and bad points of this system of socialized medicine are evaluated by the authors with an attempt to predict the future. It is obvious that they consider it a most interesting experiment, worthy of extension.

The book is a valuable summary of information much of which has previously appeared in magazines and books.

The medical reader will wish that the first half had been reduced and the second half given more extensively. As a "Sketch" it is recommended to all.

ANNA DEAN DULANEY

Diseases of the Heart—By Sir Thomas Lewis, M.D. New York: Macmillan, 1933. 297 pp. Price, \$3.50.

This well written book carries out essentially what the author states in the preface as his intention; *viz.*, simplicity in teaching. It does not pretend to be a treatise upon all the phases of cardiac pathology, and much in the way of theory has been left out. The classification of the diseases of the heart is necessarily anatomical in certain instances, yet the physiological viewpoint is always borne in mind. The author in his discussion keeps before the reader the idea of Sir James MacKenzie—to use one's own special senses and sound clinical observation as a means of diagnosis. The use of the electrocardiograph is not emphasized, though it is by no means deprecated. Where it is necessary to make a point clear, electrocardiograms are used. All the while, the needs of the man in general practice who may not have at his disposal elaborate mechanical aids, is kept in view, and the author gives in a very clear manner the points which he wishes to make.

The use of elaborate and many times confusing technical terms is avoided. Of special interest are the chapters on cardiac failure, coronary thrombosis, and angina.

One chapter given to the discussion child-bearing, anesthetics and operations, is especially timely, as very few authors take the trouble to consider these subjects except in the most casual manner. His discussion of these subjects is most helpful to the general practitioner.

This book can be recommended to every physician whatever may be his

specialty, for heart disease in one way or another touches every field of medicine. It supplies the need for the one who wants accurate, well classified information in a hurry and who does not wish to have it cluttered with nonessential details.

The book is well printed and put together. The illustrations, though not very abundant, are excellent.

EDGAR D. BASKETT

Annual Report of the Surgeon General of the Public Health Service of the United States for the Fiscal Year 1933—Washington: U. S. Government Printing Service, 1933. Price, \$0.75.

This report is shorter than usual. It is known that funds have been cut and personnel reduced, with the necessary curtailment of activities. However, the report is encouraging.

The report begins with a review of world health conditions which necessarily affect us, though we have been fortunate through our quarantine service in keeping epidemic diseases from our shores. Plague continues to be the most imminent menace of all diseases. India had 38,000 deaths from plague in 1932, an increase of about 10,000 over 1931. Typhus fever has been somewhat prevalent in Mexico, and an outbreak of some 955 cases has occurred in this country, confined largely to 3 southern states which recently took up the extensive culture of peanuts.

In the United States the health conditions have been good, the general death rate for 1932 being the lowest ever recorded, and those for tuberculosis, diphtheria, and typhoid fever have also reached new low records. There were some increases in the death rate from the degenerative diseases, such as cancer, heart diseases, etc.; but this is only a continuance of what has been happening for some years. In

spite of the distressing economic conditions, unfavorable results have not yet become apparent in the crude death rate, though it has been shown that there is increase of illness among the unemployed, whose economic condition is therefore below par.

The infant mortality has decreased. In 1915, 1 infant out of every 10 born died in the first year, while in 1932, only 1 out of every 17 died. Against this, the birth rate has continued to decline, being now 17.3 per 1,000 population.

Smallpox has decreased, but is still one of the blots on our record. More than 400 cases of cholera were reported in the Philippine Islands, but it did not reach this country. Rocky Mountain Spotted Fever continues to be a menace in the Rocky Mountain and Pacific States, and 103 cases, with 10 deaths, were reported on the Atlantic seaboard. Pellagra has decreased from 7,074 deaths in 1924 to 4,091 in 1932, but many health officers anticipate an increase due to poor economic conditions. Undulant fever continued to attract attention, 1,502 cases, with 71 deaths, having been reported in 1932.

The usual quarantine service has been carried on efficiently, 10,935 vessels having been inspected on arrival at domestic ports, and 2,982 at insular ports, while in foreign ports, 179 vessels were inspected before sailing. An interesting feature and one that is comparatively new, is the inspection of airplanes, 4,186 of which arrived at air ports from foreign lands, carrying 25,767 persons. Owing to the lack of personnel, 1,977 entered without the examination required by law. Inspection of airplanes failed to reveal the presence of any disease-bearing mosquitoes in those which had been sprayed during the flight with an oil extract of pyrethrum flowers, though experiments have shown that planes could

and did carry such mosquitoes alive when this precaution was omitted.

During the year a beginning was made on two narcotic farms, one at Lexington, Ky., and one at Fort Worth, Tex.

The Service has moved to its new building on Constitution Avenue and 19th Street, N. W. An interesting history is given of the housing of the Service since its establishment in 1798. Among important matters in which results have been achieved are those on malaria, in which county-wide dusting at 21-day periods has been carried out in an effort to suppress the disease. Studies have also been made on plasmochin and atabrin, the latter of which have been extremely promising. It seems to be superior to quinine, acting somewhat more quickly and without discomfort to the patient. In coöperation with the State Hospital for Insane, Columbia, S. C., Dr. Mayne has established strains of benign tertian, quartan, and a relatively mild strain of estivo-autumnal malaria. Shipment of live mosquitoes and blood as well as sporozoites from the salivary gland has been carried out successfully.

The Service has carried on extensive studies on hemolytic streptococci and has developed a streptococcus toxoid for immunization against scarlet fever which has been successful in a series of 3 doses in over 80 per cent of 1,700 persons. Diphtheria studies have been continued, and it is announced that the alum precipitated toxoid in a single dose of 1 c.c. is at least as effective as 2 doses of 1 c.c. each of the original unmodified toxoid. It seems entirely probable that this treatment will supersede other prophylactics. Altogether, the report is encouraging, and should be read by health officers and those interested in the state of the public health.

MAZÛCK P. RAVENEL

Outline of Immunity—By W. W. C. Topley, M.A., M.D., F.R.C.P., F.R.S. Baltimore: Wood, 1933. 416 pp. Price, \$6.00.

This book does much to remedy the unsatisfactory position of Immunity as a subject, to which the author refers in the preface. It is a systematic and condensed presentation of an immense amount of material. While a considerable proportion of the printed contents and illustrations have already appeared in *The Principles of Bacteriology and Immunity*, written by the author and his associate, Professor Wilson, these parts have been revised and either condensed or extended. In the present form the book serves as a specialized text for the advanced student, with a sound foundation in clinical bacteriology. It is in no sense a reference book to be recommended to the beginning student.

The contents, which cover thoroughly the field of immunological interest, include discussions of infection, the mechanism of bacterial invasion and varied defenses of the host, the antigenic rôle of bacteria, with a consideration of their chemical make up, herd immunity, virus immunity. Especially clear are the accounts of the responses of bacteria to the defense mechanisms of the host and the origin of natural antibodies.

Four chapters of the book deal with the practical application of immunity in diagnosis, in prophylaxis, and in treatment, and the standardization of immunological reagents.

At the end of each chapter a concise summary of the important points is given in numerical order with the list of references following.

The term "mechanism" is a favorite one with the author, and data are critically considered from this point of view. The facts are impartially stated and while the author in no way evades

personal opinions, these are given in manner devoid of dogmatism.

The general make up of the book is pleasing. It offers sufficient "reason" for having been written.

ANNA DEAN DULANEY

Industrial Health Service—By *Leverett Dale Bristol, M.D., Dr.P.H., Health Director, American Telephone and Telegraph Co. Philadelphia: Lea & Febiger, 1933. 170 pp. Price, \$2.00.*

This handy little book is all that its name implies. It presents in a condensed form the more important facts with reference to the health of workers in industry, and these from three standpoints—the management, the supervisor, and the individual himself. The book is accordingly divided into three parts with brisk, short chapters composing each.

While there are no illustrations or formal tables, there is a good index as well as two appendices carrying appraisal forms, the one for smaller industries and the other for personnel and industrial relation services in general.

It is interesting to note that a suggested appraisal form for industrial hygiene was presented to the Committee on Standard Practices of the American Public Health Association some years ago, but, so far as the reviewer knows, this is the first attempt to give definite form to such an idea after a presentation of some parts of it to the Section on Industrial Hygiene (at the Washington Meeting in 1932).

Examination of the substance matter of various chapters shows that the work is quite up-to-date, quite in keeping with the best thought, and something which those interested in industrial health efficiency should be glad to have available for ready reference.

EMERY R. HAYHURST

Contagious Diseases—What They Are and How to Deal With Them—By *W. W. Bauer, M.D. New York: Knopf, 1934. 218 pp. Price, \$2.00.*

This book written for the layman deserves more than usual commendation. It is easily understandable to the average mother for whom it is written specially. The last part of the book is not so good as the first. In our judgment, there are two outstanding faults: Toxin-antitoxin is still mentioned, and there is no mention of alum precipitated toxoid, although this is on the market and bids fair to supersede all other preparations, and certainly toxin-antitoxin. The second criticism is that the treatment of prevention of tuberculosis is entirely inadequate. There is practically no mention of the danger of bovine tuberculosis to human beings, though it is universally recognized not only as a cause of death, but a still greater cause of disability.

The book is well written and well printed, and we hope for it a wide circulation.

MAZYCK P. RAVENEL

Behind the Doctor—By *Logan Clendening, M.D. New York: Knopf, 1933. Price, \$3.75.*

Many readers of newspapers will recognize the author of this book as the writer of daily health articles which are familiar through the pictures of Dr. Clendening which always accompany them.

The same type of readers will find this book interesting and instructive for it has been written for the layman. Scientific facts are there, but these are greatly embellished by fictional dialogue and a gossipy style that will lead the layman to believe that scientific discoveries and medical advancement are veritable romance, that the men concerned were very human creatures.

The author justifies the fictional form by the expressed belief that medical discoveries in the form of straight historical narrative would not appeal to the type of reader for whom the book is intended. The sprightly conversation, the intimate glimpse into personal lives are either "extracted from their own writings or are reasonable deductions from those writings of what the character would have said." In any event, it is a rather gay account of the many discoveries and tremendous background of knowledge which goes into the making of the present-day doctor.

There is a brief account of the beginnings of medical knowledge—the medicine man with his final displacement by the fathers of modern medicine, Hippocrates and Galen. Then follow sections dealing with the early development of the fundamental sciences, anatomy and physiology, and the resulting influences in treatment of disease; preventive medicine and vaccination, the entrance of laboratory examinations into medicine, the development of modern medicine and surgery, and the progress of all branches of medicine since 1900.

A bibliography giving references for

each chapter, and citing the places where the writer has "wandered without guidance or authority," closes the book. There are numerous photographs and original drawings which add to the attractiveness of the epic.

The book is without doubt very interesting and much real information may be obtained. The style is more interesting while reading page 1 than when pages 200 or 300 are reached, by which time it seems a trifle facetious and too "popular."

The subdivision of the chapter on Preventing Plague and Pestilence headed "The Dear Little Boy" turns out to be an account of Edward Wortley Montagu, Jr. Oliver Wendell Holmes's appreciation of the many sources of medical knowledge is elaborated upon in chapters describing, "What Medicine Learned from a Sailor," "What Medicine Learned from an Old Market Woman," "What Medicine Learned from a Postmaster," "What Medicine Learned from a Singing Master."

The book is beautifully gotten up, with heavy paper and good type. As a dramatized account of medical progress in very readable form it is recommended.

ANNA DEAN DULANEY

BOOKS RECEIVED

OUR COMMON ENEMY: COLDS. By Editors of "Fortune." New York: McBride, 1934. 102 pp. Price, \$1.00.

BLINDNESS AND THE BLIND IN THE UNITED STATES. By HARRY BEST. New York: Macmillan, 1934. 714 pp. Price, \$6.50.

ALCOHOL. ITS EFFECTS ON MAN. By Haven Emerson. New York: Appleton, 1934. 114 pp. Price, \$1.00.

HEALTH EDUCATION IN AN AMERICAN CITY. By Louise Franklin Bache. New York: Doubleday, 1934. 116 pp. Price, \$2.00.

PEDIATRIC NURSING, INCLUDING THE CARE OF THE WELL INFANT AND CHILD. 3d ed. By Gladys Sellw. Philadelphia: Saunders, 1934. 609 pp. Price, \$2.50.

HEALTH THROUGH THE AGES. By C.-E. A. Winslow and Grace T. Hallock. Metropolitan Life Ins. Co., 1933. 64 pp. Free to junior and senior high school classes.

NATURE, M.D. HEALING FORCES OF HEAT, LIGHT, WATER, ELECTRICITY AND EXERCISE. By Richard Kovacs. New York: Appleton, 1934. 181 pp. Price, \$2.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Iconoclasts Air Views on Health Examinations—"The Periodic Health Examination is a procedure which will occasionally reveal early remediable diseases. It is a luxury and should be paid for as other luxuries. . . . The examination provides an opportunity to discuss hygienic habits of the individual and to educate him in the value of investigating any recently acquired trivial signs or symptoms. From this leads our (Committee on Public Health, Massachusetts Medical Society) conclusion: that universal investigation of recently acquired trivial signs and symptoms by the family doctor would be more profitable than the periodic health examination, and that it should be substituted for the periodic health examination in future propaganda."

ANON. The Periodic Health Examination. *New Eng. J. Med.* 210, 4:225 (Jan. 25), 1934.

Does Impeded Drainage of the Breast Cause Cancer?—Of 200 cases of mammary cancer, only 8 per cent gave a normal nursing history, or a history free from factors causing impaired drainage; every third pregnancy had ended in a miscarriage or abortion. In the control group, one 1 in 7 pregnancies ended this way, while 80 per cent gave a normal nursing history.

ADAIR, F. E. Etiological Factors of Mammary Cancer in 200 Women. *New York State J. Med.* 34, 2:61 (Jan.), 1934.

Skin vs. Bacteria—"Living bacteria placed on the skin rapidly disappear from this surface. They cannot be demonstrated by cultural or tinctorial methods 30 or 40 minutes after contact with the surface of the skin."

ARNOLD, L. and ALEXANDER, B. The Self-Disinfecting Power of the Skin. *Am. J. Hyg.* 19, 1:217 (Jan.), 1934.

Varied Pictures of an Influenza Epidemic—Immediately after the 1928 influenza outbreak, surveys were made in 14 cities and the result analyzed in relation to age, sex, and color. Probably the most valuable findings will be seen in the variation in extent and severity in the several communities studied.

COLLINS, S. D. The Influenza Epidemic of 1928-1929 in 14 Surveyed Localities in the United States. *Pub. Health Rep.* 49, 1:1 (Jan. 5), 1934.

What Makes the Vitamins Tick—The first of three excellent lectures on vitamins deals with their biochemistry. It is to be regretted that it appears only in a British journal and will not be available to all health workers for, though the chemical discussion will be quite beyond the comprehension of all but a handful, the reading would be worth while for all if only to disabuse our minds of any parochial ideas that the sum total of scientific advance is confined to the United States. The second and third lectures deal with the physiological functions of vitamins and the eminently practical problems of human nutrition. The author's thesis is that there is terrifying evidence of malnutrition despite the fact that there is not a large number of people actually short of food. When Englishmen were raised chiefly on coarse bread, cheese and beer, malnourishment was less rife than it is today, he tells us.

DRUMMOND, J. C. Modern Views of Vitamins and Their Functions. *J. State Med.* 42, 1:3 (Jan.), 1934.

Safeguarding Milk and Getting It Consumed—How Louisville enacted and enforced the standard milk code and boosted the consumption of milk

produced under it is recounted with sufficient detail to make the record of value to others.

DUGAN, S. H. V. Pure Milk Problem. *Municipal Sanitation* 5, 1:13 (Jan.), 1934.

How to Find Undernourished Children—To aid in sorting out school children who should be seen by a physician, an index is proposed which is better than height-weight-age and other criteria of nutritional status. Three simple measurements: arm girth, chest depth, and hip width, are used to screen out the undernourished children who are subjected to more extensive tests or sent directly for medical examination.

FRANZEN, R. and PALMER, G. T. The A.C.H. Index of Nutritional Status. *Child H. Bull.* 10, 1:26 (Jan.), 1934.

Tuberculosis Aggravated by Silicosis—Four papers from the annual meeting of the N.T.A. are supplemented by another, on the roentgenological aspects, to form a symposium on the relationship of silicosis and tuberculosis. The series presents much that is new on the subject; hence it is an important addition to the literature of industrial hygiene.

GARDNER, L. U., LANZA, A. J., *et al.* Silicosis (etc.). *Am. Rev. Tuberc.* 29, 1:1 (Jan.), 1934.

A Good Word for Russian Public Hygiene—How women and children are cared for under the Russian scheme of socialized medicine is told with sufficient thoroughness to excite the inevitable high-powered debate.

KINGSBURY, J. A. Russia Demonstrates Socialized Health. *Pub. Health Nurs.* 26, 1:5 (Jan.), 1934.

Where Health Insurance Has Been Tried—No country in which a scheme of compulsory health insurance has been adopted has ever abolished it. Criticism has not been lacking, but it is directed against practices not the

principle, which is now approved by the International Medical Association Council.

McCLEARY, G. F. Health Insurance in Europe. *Milbank Quart. Bull.* 12, 1:3 (Jan.), 1934.

Dust Particles Injected Into the Body—Dusts of different kinds were injected intraperitoneally into guinea pigs. Calcium dusts were absorbed without producing scar tissue; quartz and flint produced nodules which continued to increase in size; soapstone, coal, etc., were inert in reaction. This response may be used for the classification of industrial dusts.

MILLER, J. W. and SAYERS, R. R. The Physiological Response of the Peritoneal Tissue to Dusts Introduced as Foreign Bodies. *Pub. Health Rep.* 49, 3:80 (Jan 19), 1934.

What Nurses Ask For—"In the health officer she expects superior knowledge of public health needs, leadership in defining policies, interpretation of scientific facts, guidance in adapting public health procedures, coördination of all community health activities, popularization of her services, a connecting link and buffer to the medical profession, a health educator, and an executive who understands and appreciates the individual"; a large order!

MILLER, R. K. What the Nurse Expects of the Health Officer. *Pub. Health Nurs* 26, 1:16 (Jan.), 1934.

Diabetes Increases Tuberculosis Susceptibility—Pulmonary tuberculosis occurred 10 times more frequently in juvenile diabetics than among normal children, and the incidence of tuberculosis among adult diabetics is increasing despite a reduction in community contacts. Does diabetes lower resistance to tuberculosis? This and some other questions are studied.

ROOT, H. F. The Association of Diabetes and Tuberculosis. *New Eng. J. Med.* 210, 1:1 (Jan. 4), 1934.

NEWS FROM THE FIELD

RESOLUTION ADOPTED BY THE SOUTHERN MEDICAL ASSOCIATION AT ITS RICHMOND MEETING

DR. William Weston, Columbia, South Carolina, a past member of the Council, accompanied by Dr. Robert Wilson, Charleston, S. C., a past president of the Association, appeared before the Council and presented the following resolutions:

WHEREAS, Investigations reveal information that nutritional deficiency is constantly assuming a more important rôle as the etiological factor of many diseases that have heretofore not been understood; and as it is now known that there are present in the United States a great many diseases belonging to this group, some of which diseases are widespread, increasing in number and are seriously undermining the health and vitality of the people of this country; and

WHEREAS, We have little definite knowledge of the chemistry of our foods, because analyses which have been made in order to determine their nutritional value have been local or sectional and no sustained effort has been made upon a broad scale to supply such information as is necessary in order to determine the localities from which our food supply should be drawn; and,

WHEREAS, It is known that in certain localities and under certain circumstances, the chemical elements of common foods, such as milk, fruits, vegetables and cereals, show marked differences in value while it is known that in other localities certain vegetables absorb poisonous substances which render them of doubtful food value; and

WHEREAS, no real progress can be made in the solution of nutritional deficiency diseases until chemical analyses of foods are made upon a broad and impartial scale and the relationships of the different chemical elements studied with scientific care; and

WHEREAS, The whole scientific world is aroused to the importance of this fundamental work in order that grave public health problems and the vitality and strength of the people of this nation be safeguarded;

THEREFORE, BE IT RESOLVED,

(1) That the Federal authorities be urged to undertake this work upon a broad, com-

prehensive and impartial scale in collaboration with selected medical colleges in the different sections of the country.

(2) That the Southern Medical Association urge that this work be undertaken at the earliest possible moment.

(3) That the Southern Medical Association request the coöperation of all other state and national medical associations in this country.

(4) That the Southern Medical Association appoint a committee whose duty and purpose it shall be to confer with the National authorities at the earliest possible moment and proceed with the work.

The resolutions were unanimously adopted, Dr. William Weston to be the Chairman of the special committee provided for in the resolutions, the two other members of the committee to be selected by the Chairman in conference with the President. The Chairman with approval of the President appointed as the other two members of this Committee: Dr. M. P. Ravenel, Columbia, Missouri; and Dr. J. E. Knighton, Shreveport, Louisiana.

The report of the Board of Trustees, incorporating the report of the Secretary-Manager, was received, discussed, and unanimously approved.—*South. M. J.* Jan., 1934, pp. 70-71.

NATIONAL COMMISSION ON CORRECT DIET

THE National Commission on Correct Diet appointed by the Government of Uruguay a few years ago has recently been conducting a campaign for the purification of the milk supply. The commission supervises the production, pasteurization, and handling of milk in different places and takes part in the enforcement of the municipal regulations concerning milk in Montevideo. The commission has also been active in teaching dietetics to the public, and particularly to school children, and

it has made a study of the nutrition of school children in the interior of the country. Members of the commission have given lectures on dietetics in the 12 child-health centers in Montevideo and in other child-welfare institutions.—*Boletín de la Oficina Sanitaria Pan-americanos*. Washington, Sept., 1933.

AMERICAN SOCIAL HYGIENE ASSOCIATION ELECTS NEW OFFICERS

THE annual business meeting of the American Social Hygiene Association was held January 31, at their offices in New York. Officers were elected as follows:

Honorary President, William H. Welch, M.D.; President, Edward L. Keyes, M.D.; Vice-Presidents, Roscoe Pound, Eugene L. Bishop, M.D., Ray Lyman Wilbur, M.D., and Mary E. Woolley; Treasurer, Timothy N. Pfeiffer; Secretary, Mrs. Henry D. Dakin.

The month of March, 1934, marks the 20th anniversary of incorporation of the Association, which began its work under the guidance of President Charles W. Eliot, John D. Rockefeller, Jr., Henry Lee Higginson, Grace M. Dodge, and a distinguished group of directors.

SOUTHERN MEDICAL ASSOCIATION TO MEET IN TEXAS

THE next meeting of the Southern Medical Association will be held at San Antonio, Tex., from November 13 to 16, 1934.

NEGRO EDUCATION

THE Office of Education of the U. S. Department of the Interior is for the first time calling a National Conference on Fundamental Problems in Negro Education, to be held at Washington, May 1-6.

One of the problems to be discussed is the problem of education as it relates

to Negro health. The conference will attempt to understand the relations of the educational problems involved in the professional education of Negroes, student health education, and child health. The subjects of vocational guidance, citizenship, and home life and health will be studied.

PERSONALS

GRACE M. COFFMAN, formerly director of the Tacoma, Wash., Public Health Nursing Association, is the new Assistant Director on the staff of the National Organization for Public Health Nursing, New York.

LOUISE M. TATTERSHALL, for almost 10 years statistician of the National Organization for Public Health Nursing, New York, has resigned to accept a statistical position with the Children's Bureau in Washington, D. C. Mrs. Anna J. Miller, formerly with the American Child Health Association, has been appointed temporarily to fill Miss Tattershall's place.

JAMES E. PERKINS, M.D., DR.P.H., has been provisionally appointed epidemiologist on the staff of the Division of Communicable Diseases of the State of New York.

HUGH R. LEAVELL, M.D., member A.P.H.A., has been appointed Health Officer of Louisville, Ky. He received his B.S. at the University of Virginia, and his M.D. at Harvard. He served as interne in the Massachusetts Hospital, Columbia Presbyterian Hospital, and Johns Hopkins University. From 1930 to 1933 he was instructor of medicine in the University of Louisville.

DEATH

LINSLEY R. WILLIAMS, M.D., Fellow A.P.H.A., director of the New York Academy of Medicine, died January 8, after a long illness.

CONFERENCES

March 29, 30, 1934, Annual Meeting of the American Association of Pathologists and Bacteriologists, Toronto, Ont., Canada.

April 1-8, National Negro Health Week.

April 16-17, Eighth Annual Meeting of the Florida Section of the American Water Works Association, Daytona Beach, Fla.

April, 1934, Statistical Conference of the Royal Statistical Society and the International Statistical Institute, London, England.

April, 1934, Southeastern Section, American Water Works Association, Augusta, Ga.

April 16-20, 1934, Eighteenth Annual Clinical Session of the American College of Physicians, Chicago, Ill.

April 23-27, Biennial Nurses' Associations Meeting. American Nurses' Association, National Organization for Public Health Nursing, and National League of Nursing Education, Washington, D. C.

May 1-6, National Conference on Fundamental Problems in Negro Education, Washington, D. C.

May 13-19, 38th Annual Convention of the National Congress of Parents and Teachers, Des Moines, Ia.

Methods for the Microbiological Analysis of Butter*

E. H. PARFITT

*Dairy Department, Purdue University Agricultural Experiment Station,
Lafayette, Ind.*

DURING the past few years the routine analysis of butter for yeasts, molds, and bacteria has increased, due no doubt to the widening application it has as an index to sanitary conditions and the efficiency of the manufacturing processes in the creamery. Because of this interest there was appointed in the American Dairy Science Association a committee to study the methods used and with the hope that they could suggest what later would develop into a standard procedure. This committee consisted of Dr. B. W. Hammer of the Iowa State College, Dr. E. G. Hood of the Dairy Research Laboratories of the Dominion of Canada, Dr. H. Macy of the University of Minnesota, and myself as chairman. The first work of this committee was to get together the existing methods and study them, and a report was issued on this work in 1930.⁵ Three years later⁶ another report was issued, and those who have read these two reports have noted changes. These changes were a result of experimenta-

tion. Another objective that this committee has been mindful of is to suggest those procedures which will give only the truest microbiological analysis, and it has, as far as possible, kept the number of suggestions as to methods at a minimum, realizing that the fewer the more likelihood of uniformity. An insight into some of the research done by this committee and its associates may improve your laboratory practice, and the committee will also appreciate aid in perfecting these methods. Methods of sampling and care of samples prior to analysis are omitted from this discussion, for there has been but little controversy as to these methods suggested in 1930.

Of the routine analysis made on butter, probably the most common is the determination of the number of yeasts and molds. The number of yeasts and molds in butter reflects the efficiency of pasteurization—for proper pasteurization destroys most of the yeasts and all of the molds—and the sanitary conditions under which the butter is manufactured. Improperly cleansed and sterilized equipment gives high yeast and mold content. Standards as to numbers of yeasts and molds to be

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

TABLE I

COUNTS OF YEAST COLONIES FROM BUTTER SAMPLES ON MEDIA OF DIFFERENT pH VALUES

Sample	pH 3.0	3.4	3.8	4.2	4.6
2	142	156	179	189	183
6	131	156	179	144	135
10	95	81	69	83	99
20	132	133	133	147	124
23	286	410	440	462	445
27	17	46	42	39	52
30	236	217	241	252	291
34	165	187	179	189	186
38	13	28	28	32	28
43	193	302	288	307	290
53	112	132	121	130	124

allowed in butter have been suggested, and in Canada a score card for grading butter is used which allows points if the number of yeasts and molds is below a definite number. The technic of making this count had not been studied in detail until a few years ago.

In 1928, Hood and White¹ made a study of the various methods used to determine the number of yeasts and molds in butter. They studied 8 media and found that the pH used by different workers varied from pH 3.5 to 4.6. The counts secured on the media adjusted to pH 4.6 were much higher than those on the media adjusted to pH 3.5, the probable reason being that at pH 4.6 many bacterial colonies developed and these were counted as yeasts, since subsurface yeast colonies are difficult to differentiate from bacterial colonies. The media used were supposed to be specific for yeasts and molds.

The evidence secured indicated that a pH of 3.5 was necessary if one was to be reasonably assured that all bacterial colonies were to be inhibited. The question arose as to whether pH 3.5 would not be inhibitive to some yeasts and molds. White and Hood² made a study of 63 representative yeast cultures secured from a wide range of Canadian butters, and found that their growth on malt agar was not adversely affected at a pH range of 3.4 to 4.6. In the study of the effect of pH on

the yeast count of butter they procured somewhat similar though not quite identical results.

The general trend, as shown in Table I, was that the number of colonies decreased as the acidity of the medium increased, though the variations in yeast and mold counts at pH 3.4 to 4.6 are not great enough to be of practical significance in routine analysis of butter.

Hood and White used in this work dehydrated malt agar, Difco. The American investigators had used whey agars prepared in two different ways, rennet and by acid coagulation. Parfitt³ made a comparison of 9 media all of which had been used and recommended for the determination of yeasts and molds in butter. The media were acidulated to pH 3.5 with lactic acid and it was found that the whey agars prepared in the laboratory were quite inferior to other media in obtaining the maximum counts of yeast and mold.

TABLE II

LOG AVERAGE YEAST AND MOLD COUNT OF 32 BUTTERS

Media	Yeasts and Molds per c.c.
Whey agar rennet coagulation	712
Whey agar acid coagulation	2,172
Whey agar dehydrated	3,831
Standard nutrient agar +5% dextrose	2,130
Wort agar dehydrated	3,684
Malt agar dehydrated	3,164

The other 3 media studied, standard nutrient agar, standard nutrient agar plus 1 per cent lactose, and infusion agar plus 1 per cent lactose, yielded higher counts than whey agar prepared by rennet coagulation, but did not support as many colonies as the dehydrated wort or malt agar.

It was of particular interest to know why the whey agars did not yield as high counts as the dehydrated agars. In all probability the natural habitat of these yeasts and molds is in milk or cream, for they are associated with dirty churns and other improperly cleansed equipment. There appeared to us two possibilities,—the buffer capacity of the medium and the oxidation reduction potential intensity of the medium. If we considered the buffer capacity of the whey media it was found that those media which required large amounts of lactic acid in order to bring them from pH 6.8 to 3.5 supported the least number of colonies.

TABLE III

CUBIC CENTIMETERS OF N LACTIC ACID TO
ADJUST 100 C.C.

Whey—rennet coagulation	11.0
Whey—acid coagulation	6.5
Whey—dehydrated	2.0

Experimenting later with tomato juice agar, it was found to yield counts equivalent to those media which required but 2.0 c.c. of N. lactic acid to adjust them, but tomato juice agar required about 18 c.c. of lactic acid to adjust it from 6.8 to pH 3.5. Thus it appears that the limiting factor is not the buffer capacity of the medium.

TABLE IV

MEAN YEAST AND MOLD COUNT OF 39 BUTTERS

<i>Media</i>	<i>Yeasts and Molds per c.c.</i>
Potato dextrose agar	218
Tomato agar	225
Wort agar	179
Standard nutrient agar +2% dextrose	150

Work is in progress to determine if the oxidation reduction potential of the medium is the limiting factor.

From the results so far secured it is indicated that the dehydrated media gave the highest counts. In seeking a medium which could be prepared in the laboratory easily, and after trying several, potato dextrose agar was found to yield satisfactory results. White and Hood had used dehydrated potato dextrose agar with good success but did not recommend it because of expense.

These counts indicate that tomato juice agar is slightly superior to potato dextrose agar but not enough to justify the additional trouble and expense. Tabulating the counts of these 39 butters in the order of their placings, the same conclusions are found as from the geometric means.

TABLE V

DISTRIBUTION OF BUTTERS

	1	2	3	4
Potato	14	6	8	4
Tomato	10	14	5	3
Wort	6	7	14	3
Standard + 1% dextrose	8	9	6	9

7 butters 0 count

Potato dextrose agar gives a clear medium, and is easily prepared, requiring only potatoes and commercial dextrose. The yeast colonies are large and if brom-phenol-blue is used in place of electrometer measurements to adjust pH, the medium does not have a color which makes it difficult to adjust to the yellow green of pH 3.5. This point should be emphasized, for with malt and wort agars considerable difficulty is experienced in adjusting the medium. It has been found good practice to add 0.5 c.c. of a 0.75 per cent solution of brom-phenol-blue to the media not only to assure correct adjustment, but because yeast colonies absorb the dye, making counting much easier and reducing the number of unsatisfactory

TABLE VI

INFLUENCE OF TEMPERATURE AND LENGTH OF INCUBATION TIME ON YEAST COUNT CULTURE

Culture No.	25° C.		30° C.		37° C.	
	48 hrs.	5 days	48 hrs.	5 days	48 hrs.	5 days

21	260	267	273	285	0	0

plates due to over growing of the plate by molds.

A study has been made of tartaric, citric, hydrochloric and sulphuric acids, and it has been found that the acid used in adjusting the pH of 3.5 is a factor in the growth of yeasts and molds. The results indicate that equally as high counts are obtained with tartaric than with the other acids. An objection was found to the acids studied other than tartaric—that as the yeast and mold colonies developed they neutralized the acid, raising the pH. If an indicator such as brom-phenol-blue is put into the medium this change becomes very apparent. These organisms neutralized citric acid more rapidly than lactic and lactic more rapidly than hydrochloric or sulphuric, and tartaric the least. This point is of importance because, in plates which contain large numbers of yeast and mold colonies, there the chance is afforded for bacteria to grow due to the increased pH.

From a group of malt agar plates which had been incubated 5 days at 21° C. 18 plates were selected, 6 heavily seeded, 6 containing between 100 and 300 colonies and 6 containing less than 100 colonies. The media had been adjusted to pH 3.5 at the time of pouring with lactic acid. At the conclusion of the incubation period the pH was again determined using a quinhydrone electrode, on the plates, with the following results:

Check Plates	pH 3.50
Heavily seeded	4.51
Medium seeded	3.96
Lightly seeded	3.77

Plates acidulated with tartaric acid did not show the same decrease of pH as did the other acids.

The incubation temperature for yeasts and molds suggested in the committee's report is 21° or 25° C. for 5 days. This recommendation is based upon the work of Hood and White² who found that 25° C. for 5 days gave the highest counts. A part of their results is given in Table VI.

While it is to be noted that in most of the samples little difference was found in the 48 hours' and 5 days' count there was a noticeable difference in colony size.

The author's comments on colony size is as follows:

In the majority of cases the yeast colonies were very small after only 48 hours' incubation, and it was necessary to use a hand lens if all colonies were to be included. With some cultures, principally the pink yeasts, the colonies were large enough to count with the naked eye after 48 hours. At 5 days, however, all colonies from each culture were sufficiently large to be counted with the naked eye.

In the routine analysis of butter the total bacterial count has not had the usage that the total bacterial count in milk has had, due to the fact that starters or butter cultures are frequently used in the manufacture of butter and

by their addition to the cream the count is greatly increased and its significance becomes valueless. There are occasions, however, when total bacterial count is desired and the unpublished work of A. H. White shows that the medium yielding the highest counts was infusion agar with the addition of 1 per cent lactose. This investigator obtained equally as satisfactory results when using Bacto beef as when using infusion agar, and the Bacto product is much the easier to prepare. No comparative counts have been made using tomato juice agar or yeast extract agar for the total count.

In studying some of the specific defects in butter due to the action of microorganisms the total count is very helpful, especially if correlated with an incubation of the butter itself to determine if the defect can be intensified. It is therefore essential to use a medium that will support a satisfactory growth of most of the microorganisms. For butters made without starter, much could be determined about the methods of manufacture and the probable keeping quality if the kinds of bacteria present are determined. There are two groups of microorganisms which are the most important from the standpoint of keeping quality—the proteolytic and the lipolytic.

The determination of the proteolytic and lipolytic groups of bacteria would hardly be advisable for routine work, but frequently those in laboratories are called upon to determine the cause of a specific defect. Among butter defects caused by microorganisms are the breakdown of the protein (proteolysis) and hydrolysis of the fat (rancidity).

For the determination of members of proteolytic bacteria in butter there are suggested two methods: (1) the picking of contiguous colonies and inoculating into skimmed milk; (2) direct counting, using a medium containing casein. These two methods are at this

time suggestive, and considerably more work is needed in the making of comparisons. Probably the simplest method of determining the proteolytic types is the addition of approximately 0.5 ml. of skimmed milk to the plate just prior to pouring, infusion agar being used as a base; proteolysis is detected by a clearing around the colony. Experience is necessary to differentiate clearing due to acidity or proteolysis. It is advisable when in doubt to flood the plates with 10 per cent hydrochloric acid solution, and if the clearing remains it denotes true proteolysis. The media suggested by Frazier and Rupp⁴ has given successful results, but there is need for more investigational work. It may be of interest to know that about a year ago the Dairy Research Committee of the Empire Marketing Board drew up a set of methods for the microbiological analysis of butter. These methods were very similar to those suggested in this country and the two committees had worked independently of each other. Their recommendations on proteolytic bacteria are of interest. They suggest the gelatine plate for the determination of liquefaction and skimmed milk agar consisting of 1.5 per cent agar plus 10 per cent skimmed milk. This latter medium would meet with the approval of those who feel that the addition of peptone and other readily digestible nitrogenous substances permits protein digesting bacteria to grow without producing the clear-cut proteolytic zone.

For the detection of those organisms which hydrolyze milk fat the method suggested is one which utilizes the dye nile-blue sulphate. An emulsion (agar, water, and milk fat) is made, to which is added nile-blue sulphate and this is added to infusion agar. The milk fat globules are dyed pink which if hydrolyzed are turned to a blue. Care should be taken not to confuse absorption of the dye by the colony as hy-

drolysis for occasionally it will be found that some colonies absorb the dye and become blue.

MICROSCOPIC METHODS

The technic worked out by Hammer and Nelson and reported in *Research Bulletin No. 137* of the Iowa State Agricultural Experiment Station is well known and needs no comment. This technic is very valuable in appraising the keeping quality of a butter, and in knowing something of the flora it contains. Microscopic methods have many advantages over cultural methods and too frequently the laboratory technician

leans too heavily upon the cultural, where so many factors must be controlled in order to get a correct analysis.

Nutritive Value of Boiled and Raw Milk in Infant Feeding

WHILE there is considerable material which has been summarized by various writers concerning the absorption of the various food constituents in milk, there are few exact data regarding the influence of sterilization on the nutritive value of milk when fed to the infant.

Two healthy infants, 8 and 7 months old respectively, were fed on a measured amount of boiled cow's milk for 10 to 14 days, during the last 7 of which, the excreta were collected. The same procedure was followed with raw milk

for a fortnight. Aliquot samples of milk were collected for analysis each day during the two periods, and the intake and output of nitrogen, fat, calcium, and phosphorus in each of the 7-day periods were determined and the retention of each calculated.

The authors conclude from their results, as far as they go, ". . . there is no evidence to support the idea that the boiling of milk interferes with its usefulness as a food for infants."—Noah Morris, M.D., and Stanley Graham, M.D., *Lancet*, Dec. 9, 1933, p. 1314.

Cough Plate Examinations for B. Pertussis*

PEARL KENDRICK, Sc.D., F.A.P.H.A., AND GRACE ELDERING
*Associate Director, and Bacteriologist, Michigan Department of Health, Bureau
of Laboratories, Western Michigan Division, Grand Rapids, Mich.*

THIS paper is a report on one phase of a more general study of the problem of whooping cough control in Grand Rapids, a city of 176,700 population. To be convinced of the importance of such a study in as many centers as possible, it is only necessary to consult morbidity and mortality statistics. Approximately 6,000 deaths from whooping cough are reported every year in the United States. Most of them are among children under 5 years. The importance of whooping cough as a cause of death in this age group is well illustrated by figures taken from reports of the Bureau of Records and Statistics of the Michigan Department of Health.

occur, conscientious reporting by physicians, adequate isolation of infective cases by health departments, and the development and appropriate use of specific agents for its prevention. Our larger problem, therefore, falls naturally into several divisions, and includes: (1) an attempt to determine the practicability and value of maintaining a continuous cough plate diagnostic service in a community such as this; (2) an analysis of the applicability of the results of such a service in obtaining earlier diagnosis and a more adequate isolation and release program; (3) maintenance of a constant supply of freshly isolated cultures for study and for use in pertussis vaccine; (4) a study

TABLE I
MICHIGAN DEATHS IN CHILDREN UNDER 5 YEARS

1929	1930	1931	1932
250 Whooping cough	186 Measles	183 Whooping cough	193 Whooping cough
211 Diphtheria	171 Whooping cough	151 Tuberculosis	139 Measles
185 Tuberculosis	162 Tuberculosis	70 Diphtheria	111 Tuberculosis
111 Measles	122 Diphtheria	42 Scarlet fever	40 Diphtheria
72 Scarlet fever	53 Scarlet fever	17 Measles	37 Scarlet fever

If whooping cough eventually is brought under control, it will be due to a number of factors—including, no doubt, an earlier diagnosis of the disease and the finding of more cases that

of the cultures isolated, including serological and other reactions and, (5) an immunization study.

The data in the present report are concerned particularly with the cough plate as a routine diagnostic procedure in a public health laboratory. In Copenhagen, the method essentially as first used by Chievitz and Meyer¹ has

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

been employed since 1916 at the State Serum Institute.² In this country, its use seems to have been limited largely to special studies of whooping cough such as those of Sauer and Hambrecht,³ Lawson and Mueller,⁴ Culotta and Harvey,⁵ and the demonstration by the Cattaraugus County Health Department, reported by Kline,⁶ and to the temporary use for obtaining cultures of *B. pertussis* for study or use in vaccine. As a routine procedure in a public health laboratory, we believe the cough plate method has been quite neglected. In the Western Michigan Division of the Bureau of Laboratories, Michigan Department of Health, Grand Rapids, the cough plate diagnostic service for whooping cough has been available continuously since November, 1932.

EXPERIMENTAL METHODS

Cough plate medium—With few modifications, the original formula of Bordet and Gengou⁷ has been used. The potato-glycerine-agar base is prepared in large lots and stored in 200 c.c. amounts. This base medium is melted and blood added as needed, at which time the finished medium is dispensed into glass Petri dishes for cough plates and into tubes for stock cultures. Because of its availability in our laboratory, sheep's blood is used for enrichment—having been found as satisfactory as human blood. To each 200 c.c. of base, 30 c.c. or somewhat less than 15 per cent of blood is added. Although this is much less than recommended by Bordet or reported by other workers, it has given as successful isolation of *B. pertussis* as larger amounts and has therefore been used throughout the study. In several lots of medium, the addition of lactic acid, as suggested by Gardner and Leslie⁸ was tried but never with better results. In fact, such a medium had a tendency to darken and give less satisfactory growth.

The importance of the salt content of

the medium came to our attention early in the study, in our attempt to explain occasional lots of base which partially hemolyzed the blood and gave less satisfactory growth. By the addition of titrated amounts of sodium chloride to such a base, the difficulty was overcome. No reason has been found for the relatively small amount of added sodium chloride in the original Bordet-Gengou formula. The final content was less than 0.5 per cent—a quantity of salt dangerously near the lower level tolerated by red blood cells. By substituting 0.75 per cent sodium chloride for the 0.6 per cent solution used in the original formula, we apparently have given the necessary safeguard against occasional lots with an insufficient salt content and there has been no inhibition of clear-cut hemolysis. This modification has made more certain the bright red plate so necessary to optimum results.

Exposure of plates—As is true for any laboratory specimen, proper collection of the cough plate is important. That successful exposure of the cough plate is not an insurmountable difficulty, however, is demonstrated by the fact that the data presented are based upon the findings in plates exposed by 22 physicians, 3 bacteriologists, 20 nurses and a number of mothers. The exposed plate is held 4–5 inches from the patient's mouth during several expulsive coughs. It is often necessary to induce a cough by tickling the throat with a swab or tongue depressor, by pressing on the larynx, by a drink of ice water, or by some other device.

Examinations of plates and Criteria for the identification of B. pertussis—The plates are examined several times during the first 48 hours of incubation for molds or spreaders which might overgrow the plate. Such colonies are cut out with a sterile needle or scalpel. At the end of 48 hours the plates are examined for colonies of *B. pertussis*

and this is repeated twice a day thereafter. If *B. pertussis* has not been found by the end of 4 days, a negative report is made. The plates are incubated and observed for 2 more days, at the end of which they are discarded. In the rare instance of a positive during that time, an additional report is made.

In a nicely seeded, uncrowded plate, colonies of *B. pertussis* can be recognized macroscopically after 48 to 72 hours with a great degree of certainty. As a source of light for examining the plates the ordinary sub-stage microscope lamp with white ground glass is very satisfactory. The uncovered plate is placed over the lamp and the colonies studied with the aid of a hand lens (10x). By transmitted light, *B. pertussis* colonies appear smooth, raised, glistening, pearly, and almost transparent while the colonies of gram positive cocci in general appear duller, darkly colored and opaque. This light also reveals the zone of hemolysis which is characteristic of *B. pertussis*—a zone which is not sharply delimited but merges somewhat diffusely into the surrounding medium. In general, it may be said that the colony characteristics of *B. pertussis* on Bordet-Gengou medium are even more distinctive than are those of hemolytic or green producing streptococci on ordinary blood agar.

Confirmation of the identity of selected colonies is based upon several points. The consistency of the growth and the manner of its diffusion into water are very typical of *B. pertussis* and have been noted by Sauer.⁹ As a loop of growth touches a drop of water or saline, it spreads and shows at first a momentary clumping but, with very slight agitation, it quickly smooths into a homogeneous suspension. Stained by Gram's method, *B. pertussis* decolorizes readily—much more readily, in fact, than does *H. influenzae*. Viewed microscopically, the small faintly-stained

coccoid bacilli are scattered evenly throughout the film occurring singly for the most part, seldom in chains of even two and never observed as pleomorphic threads. Slide agglutination tests have been used frequently for the confirmation of colonies. The colony is emulsified in a drop of saline and a loopful of the suspension mixed with a loopful of antiserum, diluted 1:10, the remainder of the suspension being used as a control. Agglutination of *B. pertussis* is immediate and complete and readily observed with the unaided eye. The dried stained films, when observed microscopically, show the typical arrangement in the control suspension and definite clumps in the test suspension. These simple slide tests have proved reliable and of especial value in identifying suspicious colonies from plates too crowded or darkened by certain types of growth for the distinctive characteristics to be satisfactorily observed. In the case of less satisfactory plates, it is advisable to transplant suspected colonies to fresh medium. The resulting subculture grows sufficiently for identification within the next 24 hours.

Agglutination technic—The details of the method employed are outlined in a separate communication.¹⁰ In brief, it is essentially the technic devised by Noble,¹¹ and it eliminates the troublesome, nonspecific settling and clumping of *B. pertussis* suspensions which have stood for a few hours. The antisera used for the tests were produced in rabbits by the injection of suspensions of recently isolated cultures and according to the terminology of Leslie and Gardner¹² were Phase I sera.

General plan of collecting plates—Since the cough plate diagnostic service was first offered, a number of physicians, mainly pediatricians, have used cough plates in all cases suggesting whooping cough. During the earlier months, members of the laboratory staff also collected plates as a part of the immuniza-

tion study outlined above. The cases included in that series were for the most part in families receiving aid from the city, and therefore visited by city physicians and nurses. As the work enlarged, it became impossible for the bacteriologists to make all the required calls. In the meantime the City Health Department had found the laboratory results useful and in order to continue and enlarge the work, they offered the services of the Bureau of Public Health Nursing. Since this bureau uses the district nursing plan, it was agreed that each nurse secure the desired cough plates from welfare patients in her district. Because of her familiarity with the territory as a whole and with each family as a unit, the plan proved an ideal way of meeting the situation. The nurses, after instruction in technic, have been successful in exposing plates.

A further step was taken recently when the City Health Officer, Dr. A. H. Edwards, offered Grand Rapids physicians the services of the nurses for collecting plates from their private patients. At present, then, most of the plates reaching the laboratory are collected by a group of about 25 nurses experienced in the procedure. Copies of all cough plate reports are sent to the City Health Department, as for other communicable diseases.

EXPERIMENTAL DATA

Summary of cough plates—In Table II is a summary of the cough plates submitted to the laboratory between November 1, 1932, and September 1, 1933, classified according to clinical diagnosis.

Whooping cough cases—The cough plates from patients with whooping

cough, so diagnosed by the physician, are summarized separately in Table III.

Because of its bearing on the practicability of obtaining cough plates on young children, it may be mentioned that of the positive plates tabulated, 42 were from children 2 years old or less. Of these 42 children, 9 were 5 weeks to 6 months, 3 were 7 to 11 months, and 30 were 1 to 2 years of age. In comparison, there were 23 negative plates from pertussis patients of the same age group, taken during the first four weeks of disease. In other words, approximately 65 per cent of plates obtained from children 2 years of age or less, during the first 4 weeks of disease, were positive.

Comparison with certain other reports—The percentages used in Table III were calculated on the basis of number of plates, without regard to the fact that in certain instances, there were several plates on the same patient. Most percentages recorded in previous tabulations have been based on the number of patients found positive, disregarding the number of examinations made to obtain the result. Calculating our percentages on this basis for the sake of comparison, we include them

along with certain previous reports in Table IV.

There is no question that by more often repeated examinations the percentages could be markedly increased. Since our examinations on the 207 cases tabulated numbered 257, it is evident that the number of repeat examinations was not large.

Carrier data—Before we proceed very far with a discussion of whooping cough carriers, we feel the need for definition. For the sake of clarity in our own thinking and discussion, we consider as carriers those individuals harboring *B. pertussis* who, (a) have no symptoms—the healthy carrier, (b) have had whooping cough for more than four weeks—the convalescent or post-whooping cough carrier, and (c) have respiratory symptoms diagnosed other than whooping cough. On the other hand, the patient with an atypical cough not otherwise diagnosed and a positive cough plate, we consider not as a carrier but as an abortive case of whooping cough. The data in Table V include the findings in those individuals who, if positive, are classified as carriers according to this definition.

The only positive cough plates we obtained from 234 examined were two

TABLE IV

COMPARATIVE FINDINGS OF VARIOUS AUTHORS
PERCENTAGE OF WHOOPING COUGH CASES FOUND POSITIVE BY COUGH PLATE METHOD

Year of Report	Authors	Per Cent of Patients Found Positive Stage of Disease in Weeks						Total Cases
		1	2	3	4	5	6	
1924	Chievitz & Meyer ¹	75	57	61	45	40	9	914

1933	Kendrick & Eldering	84	78	83	31	11	0	207

As tabulated here, the week of disease given for one author is not always strictly comparable with that of another. For example, Sauer gives his results in terms of catarrhal and convulsive stages; Kristensen in terms of catarrhal and 1st, 2nd, 3rd, and 4th week of convulsive stage.

TABLE V
COUGH PLATE EXAMINATIONS FOR CARRIERS

during the fifth week after the onset of whooping cough.

The second attack—Although a second attack of whooping cough usually is considered an infrequent occurrence, 7 of the cases of this series gave a history of previous pertussis. There is, of course, always the question of the reliability of the history. The second infection in each case was confirmed by a positive cough plate. Mrs. B., age 27, had a severe second attack, and gave a history of a severe case when she was an infant. Mrs. M., age 30, had a moderately severe second attack. Her mother stated that she had had whooping cough when she was a child. Miss R., age 25, a city nurse, had an abortive case which will be described later, and said she had had whooping cough when she was about 5 years old. The other 4 cases were children. D. B., age 4½, had a typical case of moderate severity, and was said by his mother to have had a similar case when he was 1 year old. F. H. and D. H., brothers, age 4 and 5, respectively, had severe attacks and were hospitalized for several weeks, 1 child with a complication of pneumonia. The mother said they had had whooping cough 2½ years before. J. H., age 3, had a severe case. His first attack, only 6 months previous to the second, had been diagnosed by a pediatrician.

The abortive case—If we define as an abortive case an individual harboring *B. pertussis*, having respiratory symptoms but not developing the typical paroxysms, and with an attack not clinically distinguishable as whooping cough, 5 cases would be so classified, 4 of which were children who had mild coughs for 1 to 3 weeks, in homes where other children had typical whooping cough. The remaining abortive case was the nurse, Miss R., cited among the second attacks. She developed what she considered to be a bad cold accompanied by a cough which never became paroxysmal and lasted about a week. As she was interested in the cough plate method she exposed a plate from which *B. pertussis* was isolated. About 6 days later a baby in the house developed whooping cough, and as it had had no other known exposure, it was concluded that the case was contracted from Miss R. These cases serve to emphasize the value of the cough plate in detecting atypical whooping cough, as well as to point out the importance of the atypical case in the spread of the disease.

Time required for diagnosis—The time required to complete a laboratory diagnosis is an important practical consideration. In Table VI the positive results for 10 months are tabulated in terms of days required to make the report. The information was obtained

TABLE VI
INCREASE IN SPEED OF DIAGNOSIS DURING PROGRESS OF STUDY

Relative Period of Study	Per Cent of Positive Plates Reported on Various Days After Their Receipt						Total Positive Plates
	2	3	4	5	6	7+	
First 6 Months	3	43	27	13	5	10	109
	73			28			
Subsequent 4 Months	23	53	15	8	2	0	53
	91			10			

by comparing the entry date with the date of report on the filed laboratory blanks.

A practical point brought out in this tabulation is the lessening of the time required for diagnosis as the study progressed and greater facility was gained. With greater experience, there is increased facility in recognizing colonies of *B. pertussis* as soon as they appear and it becomes necessary only in relatively few instances to wait for subcultures for differentiation. During the latter part of the year, 76 per cent of all positive reports were made within 3 days, and 91 per cent within 4 days. We believe this compares favorably enough with certain other accepted diagnostic procedures.

Scrological grouping of the cultures isolated—The maximum titers observed for the various antisera used in the agglutination tests ranged from 1:1,000 to over 1:4,000, in terms of final dilution in the 0.2 c.c. rapid test; or from 1:5,000 to over 1:20,000, expressed as equivalent titers—that is, in terms of the usual 1 c.c. test but based upon actual quantities of serum and antigen in the mixtures. For the sake of closer comparability with agglutination titers as usually given, the results of agglutination tests with 149 cultures are expressed in Table VII as equivalent titers.

All the Grand Rapids cultures, the 2 from Copenhagen, those from Sauer, the Lapeer, and the Phase I cultures

TABLE VII
SUMMARY OF AGGLUTINATION TESTS WITH
149 CULTURES OF *B. PERTUSSIS*

Number of Cultures	Designation of Cultures	Titers with Phase I Serum
136	Isolated at Grand Rapids	
	94 — to 14th day of disease	1:2,500 to 1:20,000+
	40 — 15th to 28th day of disease	1:2,500 to 1:20,000+
	2 — Over 28th day of disease	1:15,000 & 1:20,000
4	Old Laboratory Cultures (1911-1922)*	Negative (1:20)
6	Received from Lansing Laboratory	
	2 — Copenhagen	1:20,000
	1 — Lapeer, 1931	1:15,000
	1 — Sauer	1:15,000
	1 — Phase I Harvard	1:15,000
	1 — Phase III Harvard	Negative (1:20)
3	Received from Dr. Sauer, Evanston, Ill. recently isolated cultures	1:20,000

* Received through the courtesy of Parke, Davis & Co., Detroit.

from Harvard, were agglutinated to a significant titer by "Phase I" serum, while the 4 old laboratory cultures and the culture labeled Phase III were not agglutinated. From the tabulated data, it is seen that the Grand Rapids cultures were isolated at all stages of the disease—94 during the first 2 weeks, 40 during the third and fourth weeks and 2 after more than 4 weeks of disease. This suggests that, at least in their agglutination response, the cultures of *B. pertussis* did not change during the course of the disease. The agglutination of all these 144 cultures by "Phase I" serum is in harmony with the findings of Leslie and Gardner¹² with 20 recently isolated strains.

GENERAL DISCUSSION

Practicability of the cough plate method—It is with considerable interest that we have analyzed the results of the first year of continuous cough plate diagnostic service. Is the procedure practicable? Before starting this study, we were well aware of the difficulties held up as a warning to any workers who might be tempted to take the cough plate seriously. As in any diagnostic procedure, there are certain difficulties to overcome in mastering the technic. After a year's experience, however, we believe the difficulties have been over-emphasized. Great stress has been placed by various writers upon the differentiation of *H. influenzae* and *B. pertussis*. With a properly balanced medium and increased experience in examining the cough plate, this problem tends to vanish. The necessity of securing a constant, uniform and adequate supply of blood has been met under our particular conditions by the use of sheep's blood. *B. pertussis* is easily isolated on a medium enriched with sheep's blood, it grows well in mass culture, it is antigenic, and it produces toxic symptoms in animals. With respect to the time required for

diagnosis, we have shown that an unreasonably long period is not necessary, and it is entirely possible that future studies of the growth requirements of the organism will materially shorten the present minimum period. An important aid in making the procedure practicable in our particular community is the coöperative plan with the City Health Department already outlined. In brief, there are no insurmountable difficulties surrounding the cough plate technic and we believe it deserves a more prominent place than it now occupies in public health laboratory procedure.

The value of negative cough plate findings—Particularly in studying the period of infectivity, we wish to know how much dependence can be placed on negative findings. It is generally true of diagnostic procedures that negative results do not carry the same weight as positive ones. We do rely on them to an extent, however, in various communicable disease release procedures. Whether negative cough plates can be used as an indicator of the probable state of infectivity of a patient at the end of his isolation period is under study. The Michigan Department of Health regulation states that, "Patients shall be isolated for 3 weeks after development of the characteristic cough." The city of Grand Rapids requires 4 weeks. During this fourth week of isolation, we are securing 2 cough plates at least a day apart. We are hopeful that this study will afford information that will help to answer the question as to whether the cough plate has a place in the release of whooping cough. It is safe to say that the value of negative plate findings increases in direct proportion to excellence in technic of obtaining plates and facility in laboratory diagnosis.

The period of infectivity and the post-whooping cough carrier—Any discussion of whooping cough is limited by the difficulty of exactly establishing the

stage of disease and the impossibility of achieving entirely adequate definition of terms. Under the conditions of our own study, we have been able to determine with sufficient accuracy the date of onset and we have, therefore, expressed the stage of disease in terms of the day or week after onset of symptoms. We realize that designations by different workers of the week of disease cannot be strictly comparable. For example, many clinicians place the date of onset of a disease at the time when symptoms are severe enough for a physician to be called or for the patient to go to bed, whereas epidemiologists set the date of onset as the time when the first indication of illness is noted. However, keeping the limitations in mind, we believe a comparison of the results of different workers with respect to the period of infectivity as indicated by cough plate findings, has meaning and yields considerable information.

By referring to Table IV it is seen that aside from the reports of Chievitz and Meyer and of Kristensen, relatively few positive findings have been reported after the fourth week of disease. The findings in general point toward the first 4 weeks of disease as including the infective period in most instances. Our positive findings suggest that most whooping cough patients are actively infectious during the first 3 weeks, a certain percentage remain so during the fourth week and most of them are non-infectious after the fourth week.

As found in other communicable diseases, there are occasional individuals who harbor the infecting organism for longer than the average period. Just how important these individuals are as a reservoir of infection in whooping cough and whether they can be located by the culture method remains to be worked out. If it were true, as suggested by several authors, that the organisms lose their virulence during the course of

the disease, the carrier would present no problem; but convincing data on this point are lacking. It seems likely that the early case offers the greatest opportunity for exposure and is the most potent source of infection in whooping cough. However, we cannot disregard the significance of even a small per cent of post-whooping cough or convalescent carriers. To go a step further and translate the findings with respect to the period of infectivity into practicable communicable disease regulations is a problem for coöperative study between health department and laboratory and one which will require time.

Indirect results of cough plate study—Besides the more direct results which we believe are being obtained by the routine plate service, there are less tangible effects which play a part in the general effort toward whooping cough control. The members of the community in general are reminded of the disease and its importance and they are impressed with its communicability. As a physician recently expressed it, "Grand Rapids is whooping cough conscious." The district nurses are on the alert for suspicious cases. With the nurses available for collection of plates, more physicians are making use of the cough plate service, and incidentally they are reporting their cases to the Health Department. This increased emphasis upon whooping cough has the general effect of encouraging early recognition and better isolation.

SUMMARY AND CONCLUSIONS

1. Cough plate diagnostic service for pertussis has been available continuously for about a year at the Western Michigan Division Laboratory of the Michigan Department of Health, Grand Rapids. It is proving a practicable procedure under the conditions existing there.

2. During the past 4 months of this service, 23 per cent of the positive

diagnoses have been made within 48 hours after the plates have reached the laboratory, 75 per cent within 72 hours, and 91 per cent within 4 days.

3. The laboratory findings are being used by the City Health Department in obtaining earlier diagnosis of pertussis and thereby, it is hoped, more effective isolation of cases in their most infective stage. The possible applicability of the results to the problem of release is under study.

4. In agreement with the reports of most other authors, *B. pertussis* could be isolated from relatively few patients after the fourth week of disease. A patient with whooping cough of more than 4 weeks' duration, who can be shown to harbor *B. pertussis*, is defined tentatively as a post-whooping cough or convalescent carrier.

5. One hundred thirty-six cultures isolated from whooping cough patients, at times ranging from before onset to the 35th day of disease, were found to fall into the same serological group.

NOTE: The authors express their appreciation of the helpful coöperation given by the different divisions of the Grand Rapids City Health Department, Dr. A. H. Edwards, Health Officer. Especial mention is made of the assistance given by Dr. L. J. Schermerhorn, pediatrician; and by B. Randall and her associates of the Bureau of Public Health Nursing.

Nutrition and Mental Outlook

"INDEED, the effect of nutrition on human physiology is so marked that one might even attribute an association between the unrest and distrust seen in the world today and the dietary which is directly affected by the economic situation. The hungry man is proverbially an angry man, and consequently discontented. It is common experience that the temperament and general outlook on life is governed by one's diet, its digestion, and its effect on the liver. The jaundiced view of

life is only an extreme expression of varying degrees of nutritional deficiency or excess. Our food refineries, tinned foods, rapid consumption of meals which we do not take time to enjoy or digest, may be affecting the mental outlook and destroying that peace and contentment to be found in adequately nourished individuals, particularly the beer-drinking, beef-eating Britisher."—J. O. Murray, M.D. The Public Health Outlook on Nutrition, *Pub. Health*, Feb., 1934, p. 164.

Immunity to Diphtheria and Response to Artificial Immunization of Children in Rural Virginia*

G. FOARD MCGINNES, M.D., DR.P.H., AND
ERNEST L. STEBBINS, M.D.

State Department of Health, Richmond, Va.

THE rate of development of naturally acquired immunity to diphtheria and its level vary in different population groups and are influenced by numerous factors of environment. Density of population has been shown to be a factor having a great influence upon the natural development of immunity to diphtheria, also prevalence of the disease and variations in carrier incidence influence the speed with which a given population becomes immunized. Climate apparently not only influences the clinical aspects of the disease but there is evidence that in warm climates natives acquire immunity earlier and more rapidly than do natives of colder climates. With possible wide variations in natural immunity in mind it seems that the determination of the immunity status of a given population before attempting mass immunization is an important administrative procedure.

In order to obtain as nearly as possible a representative cross-section of the diphtheria immunity status of children of rural Virginia, a study was undertaken in 5 different counties representing the most typical geographic, economic, and environmental differences which might influence the

development of naturally acquired immunity to diphtheria.

The variation in the immunity of children giving no history of previous immunization in these 5 different counties is shown in the age groups 5 to 9 and 10 to 14 in Figure I.

Buchanan County, having the highest percentage of Schick negative children, is a typical rural, isolated, mountainous county in southwest Virginia. With the exception of one village with a population of 800, there are no communities with over 100 persons. There were no hard surface roads in the county at the time of the study, and intercommunication is extremely limited. The population of the county in 1931 was 16,900. The death rate from diphtheria in 1931 was 21.6, the average death rate during the past 8 years was 36.4.

Orange County, having the second highest percentage of Schick negative children, is a typical progressive, farming county of north central Virginia. There are two incorporated towns of 1,381 and 462 population respectively. There is free intercommunication in the county and there has been extensive school consolidation. The population of the county in 1931 was 12,070. The death rate from diphtheria in 1931 was 0.0, the average death rate for the past 8 years was 4.0.

Pittsylvania County, having the third

* Read at the Second Meeting of Southern Branch, American Public Health Association in Richmond, Va., November 15, 1933.

FIGURE I

highest percentage of Schick negative children, is a typical county of the cotton and tobacco belt. There is one city of 22,300 population which was not included in the study. The population of the county in 1931 was 62,000, 31 per cent of which were colored. The death rate from diphtheria in 1931 was 11.3, the average death rate from diphtheria for the past 8 years was 10.0.

Arlington County is a suburban county situated adjacent to Washington on the Potomac River and is populated, to a very considerable extent, by commuters to Washington. The population of the county in 1931 was 29,100. The diphtheria death rate in 1931 was 0.0, the average death rate from diphtheria in this county for the past 8 years was 2.8.

Isle of Wight, having the lowest percentage of Schick negative children, is

in the farming section of Eastern or Tidewater Virginia. There are no towns in the county of over 1,000 population. There has been extensive consolidation of the schools. The population of the county in 1931 was 13,400. The death rate from diphtheria in 1931 was 22.4, the average death rate for the past 8 years was 9.1.

The differences seen in the immunity of these different groups show quite clearly the necessity of the determination of the immunity status of any specific group when mass immunization is to be carried on. The differences in the immunity status in these counties cannot be easily explained. Approximately 10,000 children of all ages were Schick tested during the study in the 5 Virginia counties; approximately 6,000 of these gave no history of previous immunizing treatment.

Figure II shows the percentage of naturally Schick negative children in each year of age in this entire group of 5 counties. The usual rapid rise is seen in the curve during the first 6 years of life and very little increase in the percentage of Schick negative reactors is noticed in the age groups above 9 years. The roof of the curve is between 60 and 70 per cent and this roof is reached between 10 and 12 years and remains quite constant in the higher ages. It may also be seen that at 6 years (the usual age of school entrance in Virginia) about 50 per cent of the children are Schick negative. This would indicate that mass immunization of school children in Virginia without previous Schick test is not justified nor is it economical.

About 30 per cent of the children whom we Schick tested in our study had

had some form of immunizing treatment during the previous 5 years. The majority had been given toxin-antitoxin, although a few had received toxoid within the last 2 years.

Figure III shows a comparison of the immunity found in treated and untreated children in rural Virginia by years of age. The lower graph showing the percentage of Schick negative among those who gave no history of previous immunization is the same as that shown in Figure II. It is interesting to note in the treated children that there is no great change in the percentage of immunes after school age. The curve at that age is between 75 and 80 per cent, which is a drop from the original level and quite different from that seen in the group of untreated children.

In our work with alum precipitated

FIGURE II—The immunity status of rural children, with no history of previous immunization, by years of age

FIGURE III—A comparison of the immunity in children of rural Virginia according to history of previous immunization and by years of age

toxoid we have obtained 95 per cent immunity as against 60 and 70 per cent immunity obtained with toxin-antitoxin which most of these children had received. It will be interesting to observe whether this curve will remain higher in those immunized with alum precipitated toxoid than it does in this group immunized with toxin-antitoxin.

STUDY OF THE EFFECTIVENESS OF VARIOUS IMMUNIZING AGENTS

In 1913, Von Behring showed that diphtheria toxin neutralized or partially neutralized with antitoxin could safely be used for the immunization of humans. Since that time toxin-antitoxin mixtures have been used widely in the immunization of children against diphtheria and have undoubtedly greatly reduced the incidence of the disease in many groups. This method of immunization is reported to have

rendered Schick negative from 60 to 85 per cent of Schick positive children by various observers. The percentage rendered Schick negative by this method seems to depend somewhat upon the diphtheria experience of the community as well as the amount of toxin injected and degree of under-neutralization.

In 1923, Ramon showed that diphtheria toxin modified by the addition of 3 or 4 per cent formaldehyde and incubated at from 38 to 40° C. for from 4 to 6 weeks lost its toxicity but retained its antigenic properties. This product, known as anatoxin or toxoid, has been shown to be an effective immunizing agent. The degree of its effectiveness depends upon the potency of the product and upon the dosage and the time interval between doses.

As early as 1889, it was observed by Roux and Yersin that diphtheria toxin was precipitated by potash alum and

this substance was used in the purification of toxin. In 1926 Glenny, Pope, Waddington, and Wallace showed also that diphtheria toxoid was precipitated by potash alum and that the antigenic properties of toxoid so precipitated were enormously increased. Precipitation also makes possible a much greater concentration of the toxoid and the elimination of a greater amount of protein. Havens and Wells showed that one dose of completely precipitated toxoid produced an extremely high degree of immunity in guinea pigs. Graham, Murphee, and Gill report that 92.4 per cent of 185 strongly Schick positive children were rendered Schick negative by a single dose of this product and that 96.6 per cent of a group of 613 children whose immunity status was unknown were rendered Schick negative in from 2 to 6 months. Seventy-two per cent of the latter group were of preschool age.

In Virginia in 1931 the morbidity rate from diphtheria increased more than 100 per cent while the mortality rate increased about 60 per cent over the preceding 5 years. These increases occurred in spite of the fact that a diphtheria campaign had been carried on during 1928 and 1929 during which approximately 200,000 children had been

given three 1 c.c. doses of toxin-anti-toxin. This marked increase in the prevalence of diphtheria aroused considerable apprehension and served as a stimulus for a detailed study of the effectiveness of various forms of active immunizing agents.

During our study we have treated 447 Schick positive children with one dose of $\frac{1}{2}$ c.c. of toxoid containing 10 units per c.c.; 239 children with toxoid containing 10 units per c.c. with 0.2 per cent alum added; 375 children with two $\frac{1}{2}$ c.c. doses at weekly intervals of toxoid containing 10 units; 338 children with two doses at weekly intervals of $\frac{1}{2}$ c.c. of toxoid containing 10 units with 0.2 per cent alum added; 324 children with one dose of $\frac{1}{2}$ c.c. alum precipitated toxoid containing 12.5 units per c.c.; and 255 children with one dose of 1 c.c. of alum precipitated toxoid containing 12.5 units per c.c.

Table I shows the per cent of Schick positive children rendered Schick negative 6 to 9 weeks after the administration of various toxoid preparations.

There is no significant difference between the per cent of Schick positive children rendered Schick negative with one dose of toxoid with or without alum, nor is there any significant difference between per cent rendered Schick nega-

TABLE I

THE PER CENT OF SCHICK POSITIVE CHILDREN RENDERED SCHICK NEGATIVE 6 TO 9 WEEKS AFTER THE ADMINISTRATION OF TOXOID PREPARATIONS

Group	Toxoid Per c c.	Amount Given in c.c.	Number of Injections	Re-Schick Tests	
				Number Tested	Per Cent Negative
I.	10 Units	0.5	1	447	83.7
II.	10 Units with 0.2% alum	0.5	1	239	85.0
III.	10 Units	0.5	2	375	94.2
IV.	10 Units with 0.2% alum	0.5	2	338	95.3
V.	Alum Precipitated 12.5 Units	0.5	1	324	93.8
VI.	Alum Precipitated 12.5 Units	1.0	1	255	96.1

tive by two doses of toxoid at weekly intervals with or without alum. However, there is a significant difference between the per cent rendered Schick negative by one dose of toxoid with and without alum and two doses of toxoid with and without alum. There is no significant difference between the results produced by one dose of $\frac{1}{2}$ c.c. of alum precipitated toxoid and one dose of 1 c.c. of alum precipitated toxoid. As there is some difference in the age distribution in these various groups it seems advisable to take one age group where the numbers are large enough to be significant and compare the various preparations. As there is no difference between Group I and II, or between Group III and IV, or Group V and VI, they may be combined.

TABLE II

COMPARISON OF THE EFFICACY OF TOXOID PREPARATIONS FOR THE AGE GROUP 5 TO 9 AND COMBINING, FROM TABLE I, GROUPS I AND II, III AND IV, AND V AND VI

Groups	Number of Injections	Re-Schick Tests	
		Number Tested	Per Cent Negative
I and II	1	287	86.4
III and IV	2	285	95.4
V and VI	1	266	95.9

Table II shows clearly that one dose of alum precipitated toxoid is as effective as two doses of toxoid containing 10 units with 0.2 per cent alum added.

We realize that our experience is not very large and that there may be some geographical and environmental differences in the populations treated which may affect the production of immunity. In our experience there has been an apparent slight racial difference.

We realize that there are questions which may be raised concerning the details of the study. The first question, we believe, would be as to the standardization of the Schick test and the personal element in the reading of the test. All of the work has been done by the authors. We used Schick test material from one biologic firm. In order to check this material we used, as controls, heated toxin on 3,000 children. Dr. W. T. Harrison, of the U. S. Public Health Service, furnished us with a standard toxin sufficient to test 1,000 children and checked our technic. We gave two tests, one on each arm, to 1,000 children using the standard toxin on one arm and the commercial toxin on the other arm. The results checked perfectly with the two toxins. After watching us give and read 3,000 tests Dr. Harrison was satisfied with the technic used. A third question, which may be brought up, is the permanency of the immunity produced. It is our plan to follow as large a group of children as possible who have been immunized in order to determine the duration of the immunity produced by the various toxoid preparations.

Need for Uniform Practices in the Microbiological Examination of Food Products*

LAWRENCE H. JAMES, F.A.P.H.A.

*Food Research Division, Bureau of Chemistry and Soils,
U. S. Department of Agriculture, Washington, D. C.*

THE presence of microorganisms in food products, with their influence upon quality and methods of preservation, is of great importance to food microbiologists. Not only have we learned the significance of the presence of some common types of bacteria, but we have found new organisms that are responsible for spoilage in products in which their presence had never been suspected. Control over pathogenic and infectious organisms is essential, but is not enough, since the quality and safety of many foods depend upon the control of spoilage bacteria, yeasts and molds.

With greater attention being given to the microflora of widely different types of food products, the necessity for standardization of the methods of microbial analysis is apparent. This is borne out by the experience of the U. S. Department of Agriculture and other agencies in the increasing number of requests for advice as to the most reliable methods of determining the microbic population of this or that food product.

Little effort has been made to unify the procedures employed in various laboratories. The methods of sampling,

culturing, incubating and interpreting the results are matters of personal choice. Nowhere are there available detailed directions which through wide and thorough study by many workers have been simplified and standardized for general use in the examination of many of the common food products.

Because of the interest in the proper control of the manufacture and handling of foods, it is natural that a movement to standardize laboratory procedures of this type should have its inception in our Association. A committee of the Food and Nutrition Section undertook to organize the work by developing coöperation between the American Public Health Association, the Association of Official Agricultural Chemists, and the Society of American Bacteriologists. The Society of American Bacteriologists appointed a representative to follow the work and coöperate where feasible; and the Association of Official Agricultural Chemists, after amending its constitution and by-laws to include microbiologists, appointed a referee to coöperate in the work. The Laboratory Section of our Association also appointed a representative to coöperate. Thus there has been organized a group of food microbiologists representing the major organizations in the field who will coöperate closely in developing standard procedures for the microbial analysis of foods.

* Food Research Division Contribution No. 198, read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

The value of standardizing the more common tests used in microbial food analysis is apparent when we consider the wide and insistent demand for such analyses. Every state in the Union conducts some type of official food analysis, and practically all cities of metropolitan size (500,000 population or over) maintain food analytical laboratories. Many college, university, and consulting laboratories are called upon to make analyses in which they have had but little experience, either with the food products, or with the special methods required. Standardization makes available uniform and accepted methods which will simplify the microbial analysis of food products. Reproduction of results by different laboratories is readily obtainable and their interpretation easily confirmed. Further, with accepted directions available in printed form, analyses would be made in laboratories where such tests are not now made.

Selection of the types of food or the methods of analysis requiring earliest attention is a difficult matter. What appears insignificant today may be of paramount importance tomorrow. In

general, foods can be grouped into several classes, such as canned foods, dried fruits and vegetables, meats and meat products, fermented foods, and marine products, so that, for the work under way, the development of methods for each class can be placed under the supervision of a laboratory worker well qualified in that particular field. In today's program we will hear from men who, because of long experience and familiarity with their fields, have been requested to review the present status of methods for the microbial analysis of certain types of products. These topics have been selected either because there is considerable information available, or because there is a special demand for information at this time.

The microbiological aspects of foods is of great economic importance, both from the standpoint of spoilage and deterioration and from that of public health. Standardization of laboratory procedures for such microbial examination is a present necessity and not only will aid in the better protection of the health of the consuming public, but pave the way for development of new and improved methods of food preservation.

Does the Press Want Health Statistics?*

GEORGE H. VAN BUREN, F.A.P.H.A.

*General Supervisor, Statistical Bureau, Metropolitan Life Insurance Company,
New York, N. Y.*

THIS has not been a difficult paper to write. First, it asks a question, "Does the press want health statistics?" and gives the answer, which is *Yes*. Second, it points out certain types of information, based on health statistics, which the newspapers like to use—both for news items and for editorials. Third, it endeavors to tell what profit the health departments and the public health movement in general gain through the use by the newspapers of health statistics.

I asked a friend, who is a newspaper man, why the newspapers of today give so much more space to "stories" based on health and medical statistics than was the case 20 or 30 years ago. "The answer," he said, "is easy. The newspapers want news and the vital statistics people are giving it to them. Every man," he went on, "consciously or unconsciously, watches his health, and speculates on his chances for a long life. He is interested—not only in the fact that the average length of human life is being prolonged, but in the details of how this is being accomplished. And don't forget," he added, "that no element in American life is more public spirited than the American press. The newspapers are perhaps the strongest allies of the public health movement."

How then may we, the members of the Public Health Education and Vital Statistics Sections, best capitalize the willingness of the newspapers to aid in public health education through public health publicity?

I wish that I had begun years ago to keep a record of the publicity given by the daily press to health items which were based on statistical data. I would like systematically to go over the files of the newspapers to determine the relative news appeal of items which have had their source in the statistical laboratories—the news appeal, as measured by the number of times the newspapers have published items on various health topics, and the number of lines and inches of newspaper space given to each.

In the first place, let me impress upon you that every state or municipal health department should endeavor to keep its records of mortality and sickness as nearly current as it is humanly possible to do. The newspapers prefer news to history. The daily papers in any given city, for example, would like to tell their readers *early* in 1934 whether the death rate of 1933 was higher or lower than that of the year immediately preceding. They would like to print, in January, the facts about the important causes of death—for, in January, they are news, whereas in July they are merely history. Is it practicable or possible, then, for the health departments to turn out current, or nearly current

* Read at a Joint Session of the Public Health Education and Vital Statistics Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

vital statistics? Well, we in the Statistical Department of the Metropolitan Life Insurance Company do it for our mortality statistics, and we have a much larger population and a much more extensive mortality experience than any state in the country. In fact, in our Industrial Department alone, we deal with the deaths among approximately one-seventh of the entire populations of both the United States and Canada. The great City of New York does it, and the newspapers gladly print the facts given them because their timeliness gives them a definite news value.

By running back over rather fragmentary records and drawing on my recollection I am able to cite for you some of the subjects concerning which statistics have been widely published on account of their news value. It should be perfectly feasible for many state and municipal health departments to give out much similar information for their own communities. Regardless of whether your own health department is, or is not equipped to give out health particulars like those I am about to mention, I submit that all of them have a distinct public health interest. Here are some of these subjects.

1. The effect of tuberculosis on the average length of life, showing how much longer the average life would be in America if it were possible to eliminate tuberculosis. Various articles on tuberculosis with emphasis on its declining death rate, showing how this decline has been brought about; also the probability of further reduction, until tuberculosis may actually become one of the minor causes of death.

2. Heart disease as a fruitful field for preventive health work—showing the brighter side of the heart disease picture, namely, that the death rate is declining among children and young adults—and telling why.

3. Vacation typhoid — a warning against the shallow infected well, flies,

polluted milk, etc. Information of this type, obviously, should be given out shortly before the vacation season, with a reminder based on statistics, that the typhoid death rate is highest in August, September, and October.

4. Summer drownings—how to safeguard against them; methods of rescue, etc.

5. An analysis showing that poor teeth are an important cause of ill health, and that they frequently superinduce diseases which cause death.

6. Proving that public health is national wealth; that the well directed expenditure of money for the conservation of health will increase the wealth of the community more than any other equal investment of public funds.

7. A series of articles on the value of human life. These articles should stress such items as the cost of being born, of food, clothing, shelter, education, medical and dental care, recreation, etc., and point out the moral that every human being constitutes an investment and that his early death means an actual loss of money to the community.

8. What accident prevention, or reduction, means to a community.

9. What medical service in industry has accomplished.

10. Death as a factor in family damage—stressing the far-reaching consequences of the death of a parent.

11. Why tolerate diphtheria? A plea for immunization stressing the responsibility of the parents and pointing out how school superintendents can also help.

12. The value of periodic medical examinations.

13. Showing that accidental burns is the only form of violence that kills more women than men, and telling why.

14. The seasonal factor in mortality.

15. Accidental poisonings among young children, stressing, in particular, the danger which arises from leaving

pills containing strychnine where children can reach them; and the necessity for having warning signs and striking labels on containers.

16. A new field for the child welfare associations, pointing out how it is possible for the women of America to do as much to prevent accidents to children as they have done to conserve child health.

17. Child suicide. Back in 1927, there was a succession of child suicides. There was a lot of excitement about this until we in the Metropolitan gave the cold facts to the press, namely, that child suicides were, after all, of negligible numerical importance—that the actual death rate had been going down, for years, and that at the very time suicides among children were receiving so much publicity the child suicide death rate was only half what it had been 10 years before.

18. The origin of fatal accidents. How many in the home? How many in public places and in industry? Similar facts for non-fatal accidents.

19. An article on smallpox. Such an article was published in literally hundreds of newspapers because it showed that the only states where the smallpox situation had been at all serious were the very ones where our anti-vaccination friends had been the most active.

20. The prevention of maternal deaths—showing that through proper medical care and nursing two-thirds of them are preventable.

21. How cities may reduce automobile deaths. For example, questionnaires might be sent to safety officers in cities which had experienced notable reductions in fatal automobile accidents, asking how this was accomplished, and the summation of their replies given to the press.

22. An article showing that lower death rates mean fewer orphans.

23. The relation of body weight to certain causes of death.

24. Chronic lead poisoning in infancy, showing, on the basis of statements from a number of the country's leading pediatricists, that lead poisoning among infants is more prevalent than is generally known.

25. Fatal accidents in old age—where and how they occur.

26. The necessity of maintaining the public health services, Federal, state and municipal, at maximum efficiency during the depression.

27. The change in the rank of leading causes of death. Comparison with the facts of the first quinquennium of the century with the latest 5-year period.

28. Wet clothing and the common cold.

29. Showing that there has been a 40 per cent increase in life expectation within 40 years.

These are by no means all of the subjects on which it is possible to give to the press interesting, newsy information, based upon statistical studies.

Ladies and gentlemen of the Sections on Public Health Education and Vital Statistics, you possess a body of knowledge which, whether you appreciate it or not, constitutes *news*. The papers want facts like these. But here I must interject a note of warning. They do not want them in the form that they sometimes appear in your own reports. Your method of analyzing the most potentially newsy data may be scientific; but it may be excessively dull. The newspaper reporter, or the editor, is apt to be impressed only by its formidableness and to shy at the task of translating it into everyday United States. It would be a fine thing if every state health department, and that of every large city, could employ, on a part-time basis, a trained newspaper man to write "releases" for the daily press. In this way a world of public health publicity, now lost, would be forthcoming.

Now, what do the health departments gain, and how does the public health movement profit by the publication of news and editorial items on subjects like those I have mentioned? For one thing, it tends to strengthen community interest in the health services and to stimulate a public demand that they be adequately supported. Such publicity

constitutes the best kind of public health education; it tends to make the people more health-minded and more safety-minded; it thus promotes public and personal health and safety; and it is, accordingly, an important element in conserving and prolonging human life. These, I submit, are the objectives toward which we are all working.

N. T. A. Meeting in Cincinnati, May 14-17

THE preliminary program of the 30th annual meeting of the National Tuberculosis Association will be found in the March *Bulletin* of that organization, copy on request.

The program opens on Monday night, May 14, and extends through Thursday, May 17. The Clinical Section will meet in two sessions and a joint session with the Pathological Section. The joint session will be devoted to a symposium on collapse therapy treated both from the point of view of the pathologist and clinician. The Pathological Section will have three sessions. The Sociological and Administrative Sections have arranged their program in the form of a symposium. Among the topics to be discussed in the three Sociological Sections are: (a) Relative Values in Tuberculosis Work, with papers by

Jessamine S. Whitney and Bleecker Marquette; (b) Race, Sex, and Industry as Factors in the Tuberculosis Problem, with papers by C. Howard Marcy, James J. Stone and L. H. Ferguson; (c) Case-finding, with papers by J. B. Amberson, George C. Ruhland and Clarence L. Hyde; (d) Social Service in Tuberculosis Work, with papers by Paul L. Benjamin, and Ida M. Cannon; (e) A panel discussion with a group of speakers.

The Administrative Section will have two sessions including the following topics: (a) The Family Physician and Tuberculosis Control, with papers by W. S. Leathers, M. F. Haygood and John H. Peck; (b) How Effective is Health Education, with papers by Ruth Heavenridge, John Sundwall, and Mary P. Connolly. Headquarters will be in the Netherland Plaza Hotel.

Local Publicity Use of Statistics from National and State Sources^{*}

HILTON J. SHELLEY, M.D.
Health Officer, Middletown, N. Y.

IT is obvious that the local health officer is dependent upon state departments of health, upon the U. S. Public Health Service, and upon the large insurance companies for national and state statistics. He is under obligation to them for a vast and varied amount of important information otherwise unobtainable. How else could he compare his community's morbidity and mortality with that of other localities in the same class, or with the state's or the nation's as a whole? From this standpoint, he should be appreciative of the storehouses of facts opened wide to him by these organizations.

He is preparing, we shall say, for a diphtheria immunization campaign. He is familiar with the manufacture of toxin-antitoxin or toxoid and with the technicalities of administering it. But in order to convince his public of the need for the program, he will have to explain what is being accomplished in other parts of the county, the state and the nation. This information, if skillfully presented, can be made a principal feature of local newspaper items, pamphlets, bulletins, window exhibits and of talks both before clubs and person-to-person.

If he were obliged to assemble the data for such a purpose, his department

might as well give him a year's leave of absence and employ another health officer. As it is, he has merely to write his state department of health. It is as easy as that to obtain statistics on innumerable public health subjects. In fact, it is so simple that we are prone to take too much for granted the labor involved in the compilation of such statistics.

From another standpoint—that is, from the standpoint of releasing statistical news to the press—I sometimes wish the national and state organizations were less prolific. One reason is this—Health officers are coming to understand more and more the desirability of planning their publicity. We are possibly 25 years behind the times in this; certainly we are far behind the commercial agencies; but I believe we at last see the need for having a system in our publicity as well as having a system in, for instance, our schemes of communicable disease control.

The press will allot about so much and no more space to news from the public health field, except, of course, in times of epidemics. Suppose, then, a local newspaper receives simultaneously one news release from the state, or the U. S. Public Health Service, or the Metropolitan Life Insurance Company, and one from the local health officer. Which will the editor consider of greater significance? The first one. Distant pastures are greenest, you know. The release may happen to be

^{*} Read before a Joint Session of the Public Health Education and Vital Statistics Sections of the American Public Health Association, at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

on the subject of Rocky Mountain spotted fever, of which disease the city never had a case. The health officer's news may happen to be of a preschool examination clinic being held preparatory to the fall term of school. Ten chances to one, the first item will be printed. Readers will thereby receive a vague impression of a disease remote to them in any case; and parents of preschoolers will miss the urgent news that here is an opportunity of learning whether or not Johnny is in fit physical condition to begin school.

From still another standpoint, I often wish the national and state organizations were more conservative in releasing statistics. It is their tendency to make health conditions appear very fine. We read something like this—"Years of life wrested from tuberculosis—Very considerable declines in the mortality from tuberculosis and pneumonia are the most important items on the favorable side of the 1933 health record, to date." (1) If you are doing public health work in the field, you will appreciate that such an item, if published inopportunistically, would not help a local health officer in an effort to increase his appropriation for tuberculosis work. Neither would it help to draw to the reader's attention the still too great incidence of both tuberculosis and pneumonia.

Or, for instance, we note this, "New low for milk-borne epidemics—The year 1932 closed with a new low record for milk-borne outbreaks." (2) Reading this desultorily, as the typical newspaper reader does, would not place him in the frame of mind to lend support in a campaign for pasteurized milk.

Or we find this, for example, "Notwithstanding the continued depression . . . the health of the people of this state during the year 1932 has in general been most favorable." (3) A local board of health might be pardoned for considering it allowable in the light of

this news to reduce its budget, even though, perchance, their health officer knew conditions in that particular locality to be much less favorable.

I am not overlooking the fact that elsewhere in these representative articles, the other side of the picture is touched upon. Nevertheless, the best angle is featured. We, as public health enthusiasts, will read all of the articles if printed in full. But what of lay readers? It is a well known fact that many persons read only the first part of news items. Furthermore, newspapers usually caption the good points and pass quickly over such news as a gradual increase in deaths from certain causes, unless it is great enough to be alarming.

People assume there is nothing to worry about. Everything is being adequately taken care of by health authorities—all of which is precisely the attitude which should not be created. The larger number of persons we can interest in public health to the extent of doing something about it, the swifter progress we shall make.

It is probably all right for the state departments and large insurance companies to emphasize the stupendous saving of lives effected by their public health activities. But how are health officers to secure funds for their work when the big boys save so many lives on paper?

There is another angle from the standpoint of news releasing by insurance companies. The lay reader fails to appreciate the point that such figures are not on an actual cross-section of the population, but are on policyholders who constitute more or less selected risks. As far as the lay reader is concerned, statistics from the state and Public Health Service, and from the insurance companies are identical.

In the publication of statistical news, I feel health officers could assist in adding local color and educational value

in the following way. If, instead of sending a release direct to the press, the large organizations would forward it first to the health officer, he could determine whether or not that particular time were the opportune time to publish it, and if so, add figures and suitable material for his community.

It seems logical that lay readers are likely to assimilate a more enlightening and useful bit of information when statistical news of a nation-wide and state-wide character is accompanied by items relating to their own corner of the world. This is on the assumption, naturally, that the health officer will present his share as well written as the others, and that he will calculate sickness and death rates on the same scale or at least with variations explained so as not to confuse readers.

You will gather from this paper that I would like to see put into effect a concurrent and well devised system of releasing statistics by the national, insurance, and private agencies and the local health departments. Statistics, being as they are a highly complex and technical subject, need to be given the public in small, timely and wisely measured doses. They are meagerly understood except by the small group who specialize in their study. Why should that group flourish before the eyes of the rank and file figures and facts which mystify but do not benefit them?

After all, public health education is the only worthwhile reason for publishing statistics for the mass. And the group of persons skilled in the art of presenting statistics educationally is as small as the group who calculate them. It seems paradoxical that organizations which would not dream of releasing any but the most mathematically correct statistics will, nevertheless, release them unrestrictedly.

What will have taken place in the releases concerning epidemic encephalitis

by the time this paper is read I do not know. But I do know that during the first few weeks of St. Louis's unfortunate experience with this disease the newspapers have carried many accounts concerning the number of cases and deaths therefrom. The following is typical of releases from state departments of health:

Figures made public by blank department of health show that for blank number of years blank number of cases and deaths were reported annually from encephalitis. The 10-year average for blank city was blank number of cases and for the remainder of the state blank number. Blank number of cases were reported during the first 9 months of 1933, and blank number for the remainder of the state. On the subject of the apparent increase in prevalence of encephalitis there has been a change in the proportion as compared with that of blank year. Prior to 1931 blank city's cases and deaths exceeded in numbers those reported during such and such a time. So on and on, *ad nauseam*. Twenty-five lines of this ended by the following vague statement: "The cases and deaths have not increased in numbers so that the changes which have taken place in the geographical distribution of encephalitis in blank state do not appear to be of any special significance."

The gist of this release could have been told in 12 words, thus: Cases of epidemic encephalitis are not on the increase in this state. The remaining 23 lines could have been utilized to brief for the reader what he actually needs to know—*i.e.*, the symptoms of the disease and what precautions if any he could take against it.

It is because of inappropriate stuff such as this, as well as the unseasonableness of many statistical releases, that I believe we need a new and better system. Such system would be directed toward making statistics not mere idle

news, but an essential part of public health education.

DISCUSSION

B. R. RICKARDS, F.A.P.H.A.

Director, Division of Public Health Education, State Department of Health, Albany, N. Y.

DR. Shelley represents, I regret to say, a comparatively small but rapidly increasing minority of health officers in New York State who appreciate the desirability, nay, the necessity of the use of publicity in order to accomplish their objectives and maintain a successful fight against opposing local forces. He is a frequent, adept, and welcome user of statistics and other data compiled by the State Department of Health. He knows what he wants to use and how to use it to best advantage. He is right that health authorities are far behind commercial agencies in this matter. We must learn to adopt such of their methods as are ethical if we are to sell health promotion and disease prevention methods to the public.

I do not altogether agree that newspapers will allot so much and no more space to news in the public health field. The amount of space they will give free depends on the amount of live, up-to-the-minute news that can be produced. That is what establishes the limits—not the available newspaper space. But this brings up the question, why should not health agencies, official or otherwise, buy advertising space? It is effective and is a legitimate charge.

I am inclined to disagree also as to which news release a local newspaper would take—one from the local health officer or one from the state, or the Metropolitan Life Insurance Company.

A local newspaper wants local news first of all. Again, it depends on the facts and how they are presented. An attempt should be made to localize general stories whenever possible. When this is done, it is almost sure to receive good publicity.

Regarding the statement relating to playing up favorable facts on mortality and morbidity—if the general health trend is favorable, you can do no less than tell the public the true situation. On the other hand, constant playing on the unfavorable side alone soon produces the reaction of crying "Wolf! Wolf!" The newspaper, in fact, is always looking for the alarming facts and will play them up to the exclusion or partial eclipsing of the favorable points.

I would, myself, like to see a more coördinated system of health news releases, but see little hope for it in the near future.

Dr. Shelley criticises an encephalitis release by a state department of health. While he mentions no names, I admit that I edited and published it. His quotation, however, is practically verbatim from our weekly bulletin, *Health News*, which is published primarily for health officials and other health workers. When it appeared in release form, it opened, exactly as Dr. Shelley recommends, with a statement that there is as yet no evidence of any epidemic of lethargic encephalitis in New York State and that the prevalence

of the disease in the state had remained low thus far.

With his further suggestion that an outline of symptoms should have been substituted for statements relating to the comparative number of cases in the

state, I certainly do not agree. Since the cases were few and no epidemic existed why unnecessarily alarm the public with a list of symptoms—useless information which the newspapers would not print under existing circumstances.

Work of the National Children's Bureau in Costa Rica

THE National Children's Bureau of Costa Rica, established in 1930, has been laying a foundation for a comprehensive system of social aid, as described in its recently issued second annual report. Several months ago the Bureau took a census of working children, particularly those in street trades; work permits and attendance at afternoon or evening schools were made compulsory for working children; and through a corps of social workers contact was established with the families of working children and of other children in need of attention. The Bureau was instrumental in the enactment of child labor regulations, and it is now enforcing these regulations. A register is kept of the children engaged in street trading and in habitual begging; each case of begging is investigated, and measures for dealing with this problem in general are studied.

The Bureau has made a survey of the neglected children and has been active in the enforcement of the school at-

tendance law as regards these children.

The Children's Bureau exercises supervision over the institutions for dependent, neglected, and delinquent minors. Among those institutions may be mentioned orphan asylums, reformatories for boys and girls, institutions for homeless or neglected girls, child health centers, children's clinics, school lunches, a day nursery, and a vacation colony for school children.

The law requires the Children's Bureau to exercise protection over the health of mothers and children, and the Bureau has already formed plans for such work.

In compliance with another law, the Children's Bureau sends representatives to testify in all court cases involving minors. It also drafts child welfare bills. The Children's Code was passed by the Costa Rica Congress soon after its introduction and is now in effect. Other bills are pending.—*Boletín del Patronato Nacional de la Infancia*, San José de Costa Rica, 3, 16-18, 1933.

Safeguards in the Publicity Use of Vital Statistics*

A. W. HEDRICH, Sc.D., F.A.P.H.A.
*Associate in Biostatistics, School of Hygiene and Public Health,
the Johns Hopkins University, Baltimore, Md.*

THERE are a number of witticisms, now worn rather threadbare, concerning the veracity of statistics and their users, which, in company with most statisticians, I should prefer to ignore in this paper. It does, however, seem desirable to allude to them, partly because they are sometimes quoted to the wrong effect, but mainly because they call attention to certain issues that merit discussion.

The first of these aphorisms, possibly from the pen of Josh Billings, says that "Figgers don't lie; but liars figger." This accusation was, no doubt, originally intended for gentry of the type of the gold-brick salesman, whose "statistics" were written on cuffs and the backs of envelopes for the benefit of his intended victim; but it is true that the charge of fallacious "figgering" applies also with considerable force to a large group of well intentioned persons.

What often happens is that an individual becomes possessed of a given conviction, and wishes to bring others to the same view; but it is not always very convincing for the propagandist simply to say: "It is my belief and that of my associates," so he seeks statistical support for his message. Statistics are complex in their meaning; Yule

has appropriately defined them as numbers affected by a multiplicity of factors. This means, for example, that the death rate of a city depends upon the age, racial, and vital state of its inhabitants; industrial, economic, and climatic conditions; medical care, public health supervision, hospital facilities, and certain distorting factors which will be alluded to later. Descriptions of other social phenomena are equally complex, whether numerical or not.

To reason correctly from such complex data is not easy, and even the most acute and careful persons will at times fall into error in the process. But no confusion can be quite so profound as that of the individual who rushes into this maze with the intention of finding support of a preconceived idea. It is truly remarkable how, under the influence of a desire to prove an *a priori* conclusion, the critical faculties of persons of honest intentions can become benumbed so that faulty data and insufficient reasons will pass muster, if favorable to the cause of the searcher, whereas antagonistic evidence will often be ignored, upon one pretext or another.

A number of years ago the writer began keeping a file of statistical errors encountered in medical and public health publications, in the hope that their analysis might be of help in his teaching. Although there are some disadvantages to the method of teaching truth by presenting error, it will perhaps be helpful to give a few examples from

* Papers from the Department of Biostatistics, No. 189. Read at a Joint Session of the Vital Statistics and Public Health Education Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

this morgue of statistical errors, to bring out certain points of this paper. As the mistakes are of a type that might and do occur to any one of us, it would be rather unfair to publish the names of the few authors who happen to fall into this particular selection; the names will, therefore, be omitted from this paper, except that I admit that one of the mistakes is my own. The first example illustrates a pitfall that has trapped more than one writer:

Example 1—A public health writer states: "In Chile, in 1911, 6 children died during the first year of life out of 20 born; . . . in New Zealand, . . . only one in 20 died. In the last named country each infant had six times as many chances to survive, as did an infant in Chile."

The statement that because the proportion who die is reduced to $1/6$ of a given value, the proportion who survive is multiplied by 6 is incorrect; it is comparable to a claim that if a frugal housewife reduces the wastage in her apple parings to $1/6$ of the original parings she will multiply her yield of apple-sauce by 6, which claim would, of course, be nonsense. Actually, since in New Zealand 1 died out of 20 born, 19 must have survived; and since, in Chile, 6 out of 20 died, 14 must have survived. The chances of surviving were therefore, in the ratio of 19 to 14, or 1.35 to 1, and not 6 to 1, as the author stated. Incidentally, even the 35 per cent advantage of New Zealand was abundantly worth while; the unconscious exaggeration was as unnecessary as it was incorrect.

The example is cited to illustrate the insidiousness of the friendly or dramatic statistics. Presumably, the author of Example 1—a man of exceptional abilities—merely did not stop to inquire into the true relationship between mortality and survivorship. If, however, the comparison had clashed with his views; if, for example, it had indicated that the nation with the more advanced health

administration had the poorer survivorship rate, the statement probably would have been challenged, and the error promptly detected.

Public health certainly aspires to as high an ideal as is professed by business: Truth in Advertising. To that end, the first safeguard proposed in the publicity use of statistics is to try to be more critical of the materials and of the reasoning which favor our cause, than of those which oppose it—*more* critical, because otherwise we shall certainly not be critical enough; the instinct to defend one's beliefs and interests is so strong that desire too often pulls the wool over the eye of reason.

ACCURACY OF STATISTICS

Although the epigram imputed to Josh Billings exonerated the figure and indicted the figurer, some unknown person said, "There are three kinds of lies: lies, damn lies, and statistics." It is, of course, important to draw a distinction between, say, the figures collected by a disinterested governmental agency, and the estimates of the newspaper reporter, the enthusiast, and the partisan.

I was once greatly cheered to hear a statistician engaged in social surveys say that he longed for data that were as complete and accurate as registration returns, such as vital statistics; nevertheless, our field does have inaccurate statement and incomplete registration to contend with. Besides these difficulties are some that arise from classification, *e.g.*, as to residence and cause of death. The residence distortion is by far the most important. As an extreme example, DePorte¹ mentions that the recorded death rate for the rural part of Dutchess County, N. Y., was more than 10 times the true resident rate, due to the presence of many hospitals and institutions.

It should be emphasized that statistics can be very useful in spite of

their inaccuracies, if used with due regard to their limitations. The current encephalitis reports, for example, may be in error by 25 or 50 per cent; yet they convey an important message. As distortions will ordinarily vary more from place to place than from year to year, it is sometimes preferable, if practicable, to make comparisons between different years than between different places.

There is an enormous difference in the trustworthiness of vital statistics of various sorts. In some instances, the compilers of these statistics have, or could obtain, tolerably good information as to the accuracy of specific statistics, and it is a great pity that this information is not oftener passed on for the benefit of the user of the statistics, for without it the statistics can indeed be most misleading.

Registrars and others are constantly laboring to improve the accuracy of their statistics, and this activity is laudable and should be encouraged. But, in my opinion, the greatest need before the vital statistics profession today is that of measuring the accuracy of their statistics, and of placing the results before those who use them. One may ask, "How can the accuracy be known if the true statistics are not known?" The answer is that the accuracy of the count may sometimes be determined from a more precise count of samples, or from related statistics of a higher order of accuracy. Examples of the determination of accuracy have been published (Refs. 2 to 7), but the ground has hardly been scratched.

For the user of statistics the second safeguard here suggested is to know the origin, meaning, and accuracy of the statistics used, or to go to some one who does know.

NUMERICAL ADEQUACY OF STATISTICS

For want of space, this subject can hardly be more than mentioned. It is

treated in most textbooks under such headings as probable error and sampling. To the casual user of statistics the following simple suggestion may perhaps be of value: An increase in the tuberculosis rate from, say, 50 to 60 per 100,000, may or may not be noteworthy, depending upon the size of the population involved. Thus, for a city of 1 million, the rates cited would imply a change from 500 to 600 deaths, *i.e.*, an increase of 100 deaths, which no sensible person would take lightly. But for a city of 10,000 the change would be only from 5 to 6 deaths. No smaller increase could be stated; the difference, although equal to 20 per cent, is clearly of little moment.

It is an excellent precaution, thus, to look at the *number* of cases, deaths, etc., as well as at the rates.

REASONING AND STATISTICS

We turn finally to a consideration of the logic associated with statistics. It was Thomas Carlyle⁸ who wrote: "A witty statesman once said that you might prove anything by figures." Carlyle was referring at the time to the inaccuracy of statistics, but a powerful inciting cause of the epigram today is certainly the loose reasoning that sometimes goes with the statistics, particularly the form of statement designated by Kant as *post hoc, ergo propter hoc*—after this; therefore because of this.

The basic difficulty behind very many errors of statistical reasoning is, I think, the tendency to consider only one, or a few, instead of all of the important factors that might affect a result. Let an example illustrate:

Example 2—An epidemiologist once went to his health officer with the statement that a certain group of beginning typhoid cases were doubtless attributable to oyster infection, since some 80 per cent of the cases gave history of having eaten raw oysters. "But," objected the health officer half jokingly, "100 per cent of them drank the city water!" (The health officer's jest had more point than he thought at the time; for it later became

apparent that the year before, there had been a small oyster-borne epidemic, and a small water-borne epidemic, concurrently.)

The epidemiologist was, of course, logically justified in suspecting oysters, but his case, as he presented it, savored strongly of *post oysters; ergo propter oysters*. The fact that oysters *might* have been responsible was no evidence that they *were* solely, or mainly responsible, and not water, milk, or other vehicles of infection. It is a fundamental theorem of scientific procedure that a given explanation cannot logically be accepted as the preferable one, unless all other reasonable hypotheses have been eliminated.

Statistical logic ordinarily improves as it approaches that of the experimental method, and the use of control populations. To revert to the last example, the hypothesis of oyster infection was more firmly established, when it was shown that the attack rate was enormously higher among consumers of Oyster A, than among controls, composed of consumers of any other brand of oyster distributed in the city. Elimination of other likely agencies of infection completed the case.

Out of the study of published errors came the interesting and constructive suggestion, that a large majority of the fallacies occurring in the use of statistical material would be avoided, if the components of even the simpler types of rates were more generally recognized, and some fairly elementary precautions taken concerning them. Even persons with extensive statistical experience sometimes come to grief for want of these precautions; the examples of this paper support this statement. In connection with ordinary time-rates, such as the death rate, it is necessary to think not only of the deaths or cases, but also of the total population universe involved, *i.e.*, the population at risk. Other important factors, though not all, are the duration, and intensity of ex-

posure to risk. Let an example illustrate the importance of focusing attention on the population at risk.

Example 3—In an examination of candidates for auto drivers' licenses, it was asked "Are accidents more frequent on rainy days than on sunshiny days: Why?"

Many persons answer that rainy days have more accidents, because of slippery roads, lower visibility, etc. Actually, however (as the examiners point out), there are more accidents on sunshiny days, the chief reason being that there are more persons in cars and on the streets on pleasant days; in other words, the population exposed to risk is larger. Another factor perhaps is that on clear days people drive less cautiously.

The next example emphasizes in another way the importance of giving thought to the population exposed to risk.

Example 4—During the decade 1910 to 1920, the mortality rate from malaria increased in the registration area about 50 per cent. Does this mean that the risk of dying from malaria in the United States really increased by that proportion?

It does not, even assuming that the accuracy of diagnosis remained unchanged during the decade. The registration area increased during 1910-1920 from 21 to 34 states. The original states were almost all in the North, and the subsequently added ones mainly in the South, where malaria is most prevalent; the addition of these malarial states caused the rate in the total to rise, hence the malaria rate in the total area rose with time. The example illustrates the importance of bringing compared populations into conformance on essentials. Not only climate, but age, race, sex, etc., should usually be considered in this precaution of making the exposed to risk populations reasonably comparable.

The last example will illustrate the importance of selecting the particular

rate which is capable of answering the question under discussion.

Example 5—It was pointed out that during recent years, the death rate for the age group 1 to 4, had declined more rapidly than had the death rate under age 1. Subsequently, another individual pointed out that this seemed to indicate the futility of infant welfare work, since the age zone of greater welfare activity showed the smaller decline in mortality.

The second person's confusion was partly due to a convention in vital statistics practice that is sometimes troublesome; namely, that of taking as the standard unit, all mortality under age 1. There are operative in that age zone two very different sets of forces for mortality. During very early infancy—certainly under 1 week of age—the dominant mortality factors are essentially congenital or prenatal. Later, however, the environmental factors enter more largely—care, feeding, and the like. Against these environmental forces, the public health campaign has, thus far, apparently been much more successful than against congenital factors. As the deaths of the first day of life, alone, now constitute, in large cities, nearly a fourth of the mortality of the entire first year, it is clear that the ordinary infant mortality rate is loaded with a heavy weight which tends to mask the effect of the life savings in the later months of infancy.

One moral from this is to refer oftener to infant mortality in several subdivisions under age 1; and if a single infant mortality rate is to be referred to, often it had best be the mortality at ages of infancy after 1 month, or possibly after 1 week.

We have seen that in each of the examples cited there was confusion with one of the several elements of a rate. In the Chile-New Zealand example the meaning of the so-called numerator population—survivors—had apparently been mistaken; in the oyster typhoid

example, the population at risk had not been contrasted with control populations; in the auto accident example the population at risk had been ignored entirely. In the malaria example, important changes had crept into the population at risk—changes which the uninitiated might easily have overlooked.

The fundamental question concerning any rate or index is: "Does it really measure the risk which we wish to discuss?" To answer this question we must scrutinize, not one, but all of the elements that enter into the rate. We have seen that in practice, fallacy hinges exceedingly often to the population universe, *i.e.*, the population in which the cases, deaths, etc., occur. It is therefore extremely important to ask: To what extent is this population really exposed to the risk under consideration? Is it suitable from the standpoint of age, race, climate, occupational hazards, and so on? Is the population large enough to be representative?

Almost anyone will, I am confident, take a long step toward the sounder use of statistics, if he will analyze in this way the elements of, say, 25 rates encountered in his reading, defining clearly each element of the rate, and evaluating its adequacy for the purpose at hand.

In summary then the following safeguards have been suggested, in the use of statistics for publicity, or otherwise. There are, of course, others of importance which cannot be discussed in a brief paper.

1. Try to be more critical of that which favors your viewpoint than of that which opposes it.

2. Know the origin, meaning, accuracy and sufficiency of the statistics used.

3. Scrutinize, not one, but all of the elements of the rates used; give particular study to the population at risk.

4. Avoid the *post hoc* method of argument; try instead to approach the experimental method, including the use of control populations.

Prenuptial Health Centers in Uruguay

CENTERS for the physical examination of persons intending to marry, called prenuptial health centers, were established in Montevideo, Uruguay, several months ago. A little later the National Council of Public Health, an official body, ordered that such a center be established at the earliest opportunity in each rural hospital or medical-aid station in the country. Measures for familiarizing the public with the work of these centers were also prescribed.

In the examinations particular attention must be paid to venereal diseases, tuberculosis, and certain other diseases, transmissible or hereditary. A

person free from such diseases is given a health certificate; otherwise no certificate is issued. The certificate must be presented to the registrar of marriages and must be noted on the marriage record. If no health certificate is presented, the registrar must suggest a physical examination, although the examination is optional.

The physician in charge of each center is required to report at certain intervals to the prenuptial health center in Montevideo, which is to supervise the work of all the centers.—*Boletín del Consejo de Salud Pública*, Montevideo, 1933, 2, 7, *Diario Oficial*, Montevideo, 1933, No. 7978.

CHART II

Both preparations of toxoid used in the above study had the same antigenic potency and both groups of children were comparable in every respect.

The stability of toxoid with alum was shown by the fact that half of our lot was stored for 7 months and results were slightly better from the older preparation than from the fresh.

A comparison is shown in Charts I and II of the results obtained by one, two, and three injections of toxoid with and without alum.

A higher degree of immunity is developed more rapidly by toxoid with alum than by toxoid without alum, a point of considerable importance at all times and particularly when diphtheria is prevalent in a community. The percentage of negatives obtained with two injections differs little from that obtained with three, and as the two injection procedure is simpler, we prefer the two injections of toxoid with alum.

Chart III shows the highly satisfactory results of two injections both with

CHART III

and without alum and the trend of development of immunization 1, 2, 6, and 12 months after. One c.c. doses produced better results than $\frac{1}{2}$ c.c. doses with but a slight increase in local reaction.

MICHIGAN TOXOID

Results from the Michigan Department of Health preparation of toxoid containing $7\frac{1}{2}$ antigenic units, were observed on 576 children.

One injection—The results of one injection of $\frac{1}{2}$ c.c. or 1 c.c. of toxoid were not satisfactory:

NEGATIVES EFFECTED BY 1 INJECTION

Interval since last injection	$\frac{1}{2}$ c.c.	1 c.c.
2 months	40%	42%
12 months	57%	61%

Two injections—The use of two injections of toxoid showed considerable improvement over one injection. One c.c. doses effected a slightly higher per-

centage of negatives after the 12th month:

NEGATIVES EFFECTED BY 2 INJECTIONS

Interval since last injection	$\frac{1}{2}$ c.c.	1 c.c.
2 months	71.0%	71.9%
12 months	82.3%	86.4%

Three injections—The use of three injections of toxoid showed considerable improvement over two injections. Apparently three $\frac{1}{2}$ c.c. injections are as effective as three 1 c.c. injections:

NEGATIVES EFFECTED BY 3 INJECTIONS

Interval since last injection	$\frac{1}{2}$ c.c.	1 c.c.
2 months	89.1%	92.1%
12 months	94.9%	95.2%

Results from one, two, and three in-

CHART IV

jections of Michigan Health Department toxoid are shown in Chart IV.

It is well known that numerous visits in connection with the immunization of a child undoubtedly prevent the family physician from becoming paramount in the immunizing problem. Until toxoid is perfected, this disadvantage might be overcome to some extent by the following procedure which we used with satisfactory results on 210 children:

The Schick test was given and, if no history of previous immunization was elicited, an injection of toxoid was given at the time of the first visit. The Schick test was read after 1 week and if positive, the second injection was given.

MICHIGAN CONCENTRATED TOXOID

At the suggestion of Young we studied the results of using a concentrated toxoid containing 30 antigenic units per c.c. on 229 children. Only two injections of the concentrated toxoid were given.

As shown in Chart III, the use of two 1 c.c. injections of concentrated toxoid resulted in a lower percentage of Schick negative children than two 1 c.c. injections of regular toxoid.

REACTIONS

In evaluating the degree and frequency of reactions a questionnaire was sent to the parents of each child immunized, requesting them to describe the nature, degree, and duration of the reactions either local or general. Redness, swelling, and pain were listed under local reactions; and headache, general malaise, nausea, vomiting, fever, and skin eruptions under the heading of general reactions.

Letters were sent to the parents of 1,456 children from whom 972 replies were received. The parents of 34 per cent failed to report, probably because no reactions were apparent.

As reactions were observed only by the parents, interpretations are perhaps not perfect, though it is reasonably certain that severe reactions were correctly reported.

Chart V shows a detailed tabulation of reactions. Toxoid with alum gives 7 per cent of moderate and severe general reactions as compared to about 4 per cent from the same preparation without alum. Moderate and severe local as well as general reactions were 3 times more frequent from concentrated toxoid than from any other preparation.

Ray, Janney, Schwartz, and others report a few instances of the development of asthmatic attacks after receiving toxoid, probably due to sensitiveness to diphtheria proteins or veal broth used in the growing of diphtheria bacilli.

In our group we observed one attack of severe character:

March 10, 1932, a boy age 10, had a Schick test with control. Reading 1 week later was positive. April 27, the child received the last injection of $\frac{1}{2}$ c.c. of toxoid without alum, followed by no local or general reaction. June 2, the child received the final Schick test. One-half hour later the lips and eyelids became swollen, the child became cyanotic and short of breath. Urticaria appeared over the entire body. The attack was relieved by adrenalin.

A similar attack was observed in a child of 3 years of age who received the Schick test in the Health Department office. Within 10 minutes the child suddenly developed urticaria all over the body, extreme restlessness, shortness of breath, cyanosis, coughing, vomiting, swelling of the eyelids and lips. Adrenalin was administered and repeated in the course of the next 15 minutes. The attack lasted over an hour. The history of this child is as follows: July 16, 1932, the preliminary Schick test was positive; subsequently he received two 1 c.c. injections of concentrated toxoid, the last being given August 23, 1932. Schick tests were given in September, and October, 1932, and in February, 1933, all of which were positive. The last which precipitated the attack was given August 12, 1933.

These attacks following the administration of the Schick test caused great

CHART V

TABULATION OF REACTIONS FOLLOWING ADMINISTRATION OF TOXOID

Preparations Used		New York City Health Dept. Toxoid				Michigan State Health Dept. Toxoid			
		With Alum		Without Alum		Regular		Concentrated	
Dose		½ c.c.	1 c.c.	½ c.c.	1 c.c.	½ c.c.	1 c.c.	½ c.c.	1 c.c.
Antigenic Units per Injection		4¼	8½	4¼	8½	3¾	7½	15	30
Number of Reports Received		186	129	112	113	235	101	18	78
Percent Reporting No Reactions		29	28	37	26	32	33	28	15
Percent of Local Reactions	Mild	67	67	59	65	60	63	55	61
	Moderate	6	7	3	8	3	3	17	21
	Severe								
Percent of General Reactions	Mild	27	28	15	20	15	12	28	17
	Moderate	6	6	4	3	1	8	17	18
	Severe		1		1	1		5	6

anxiety for a short time, though they left no sequelae. In the writers' experience with the immunization of 7,000 children these 2 cases stand alone, indicating their rarity. However, the possibility of their occurrence should not be disregarded. Park advances the theory that the toxoid sensitized the children to the material in the last Schick test and that the reaction might have been due to the endo-toxins in the toxoid or Schick toxin. As there is no knowledge of any child ever having died from toxoid or Schick toxin, these occurrences should not prejudice one against retesting. If others have had similar experiences, their publication might lead to a more thorough knowledge of the factors responsible.

CONCLUSION

1. After considerable experience with toxin-antitoxin and toxoid, we are of the opinion that toxoid is preferable be-

cause it produces a higher degree of immunity in a shorter time. As a result of our previous study of 1,282 children, four injections of toxin-antitoxin gave 74 per cent of Schick negative children at the end of 1 year, while two injections of toxoid with alum gave 88.8 per cent Schick negative at the end of 2 months and 94.3 per cent at the end of 1 year.

2. Toxoid of 7½ to 10 antigenic potency was preferable to the preparation of concentrated toxoid used by us.

3. Toxoid with the addition of 0.2 per cent of alum is a preferable preparation because it produces a higher degree of immunity as determined by the Schick test in a shorter time than any other used in this study.

4. It appears that three 1 c.c. injections of toxoid with alum would be ideal, yet for practical application two injections are sufficient.

5. A 1 c.c. dose produces a slightly

higher percentage of reactions than a $\frac{1}{2}$ c.c. dose but produces a higher degree of immunity.

The slightly higher frequency of local reactions from toxoid with alum should not be an objection because the reaction is mild and short. Moderate general reactions occurred in 7 per cent of cases.

6. In order to reduce the number of visits to a minimum, injection of toxoid and the Schick test at the same visit is suggested for children over 5 years of age whenever there is no history of previous immunization.

Essentials of Typhoid Fever Control Today*

EDWIN O. JORDAN, PH.D., Sc.D., F.A.P.H.A.
Professor of Bacteriology, University of Chicago, Chicago, Ill.

IT cannot be expected that American health workers will take as much interest today in typhoid fever as they did a few decades ago when the disease was 10 times, or in some localities 20 times, as prevalent. In many large cities the reduction in typhoid has been amazing. In Boston, in 1888, the typhoid death rate was over 40 (40.1) per 100,000; in 1932 there was only 1 death in each 200,000 population (0.5 per 100,000). In Indianapolis the typhoid death rate was 190 per 100,000 in 1905, as against 1.6 in 1932. In the face of such figures, interest in typhoid has naturally waned. At the same time we need to remind ourselves that our relative exemption from typhoid today is purchased only through eternal vigilance.

First and foremost in typhoid control comes the safeguarding of the water supply. It was one of the earliest practical triumphs of epidemiology to show that typhoid was often due to contaminated drinking water and could be largely prevented by improving the character of the supply. There can be little doubt that the main factor in the typhoid reduction of the past few decades has been the insistence of sanitarians on pure water supplies. One of the most valuable contributions yet made by American workers to the cause

of public health is the demonstration that chlorination of public water supplies is both effective and inexpensive. But for this method of purification there would without question be much more typhoid than there is today.

I am aware that there is a tendency in some quarters to view somewhat indifferently problems of drinking water control and to consider that we have successfully completed the "engineering phase" of public health and are now ready for greater conquests. The expression "environmental sanitation" has come to have almost a derogatory significance in the minds of some, as an outworn creed. It seems to me a misconception of the basis of much of our public health work and indeed of the basis of civilization itself to look upon environmental control as something already over and done with. We stand on a thin crust. It is not enough in a complicated society to start something that looks good and then leave it to take care of itself. Unceasing, meticulous, highly skilled and conscientious attention is as necessary today as ever in preventing water-borne typhoid fever.

Wolman and Gorman have done a great service by assembling in their fine monograph the evidence of the important part still played by water in the causation of typhoid fever, particularly in the smaller communities with populations of under 5,000. In states with a large rural population this is especially evident. In South Dakota, according to

* Read at a Joint Session of the Health Officers, Laboratory and Epidemiology Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

the water supply survey of 1930, nearly 50 per cent of the municipal water supplies were subject to pollution.

The excellent study by Bostrom, Hunter, and Towne of the epidemic in Chamberlain, S. D., early in 1933, where 247 cases were registered in a population of 1,530, shows that water-borne typhoid may still cause great disaster.

Responsibility for safe water supplies is likely to increase rather than diminish with the ever-growing load of pollution on streams and lakes. Emergencies will arise in the future, as they have arisen in the past, when the best judgment speedily applied will be needed to avoid a great catastrophe. It is always difficult to bring home to the public the fact that something has not happened which would have happened if precautions had not been taken against it. The newspaper reader rarely learns that he is being protected day by day from water-borne infection, but if an epidemic occurs and begins to die out in a natural way he is at once informed that the epidemic is "checked," or "under control," through somebody's heroic activities. Some day it is to be hoped credit will be given where credit is due, and the forgotten engineers and laboratory workers will be recognized as the real heroes whose unremitting labors keep most of us secure from the menace of water-borne typhoid. Environmental sanitation is not something to be laid on the shelf as shopworn and out-dated, but it is an ever-present fierce necessity without which our modern mastery of disease would soon prove to be an empty boast.

Most of the larger communities in the United States are well protected against water-borne typhoid at present by filtration or chlorination or both. Wolman and Gorman have shown, however, that approximately 40 per cent of the outbreaks of reported water-borne illness in the United States during the

decade 1920-1929 were caused by defects in the collection, treatment, storage, or distribution of the water, and not by pollution of a raw water at its source. The most important single factor during this period was the inadequately protected cross-connection between the public water system and a polluted auxiliary water service such as is often used for fire protection. It is plain that such cross-connections and similar potentially dangerous conditions should be eliminated wherever possible. Typhoid fever traced to a public water supply usually means that some one has been asleep at the switch.

In the smaller communities much can be done to improve the character of drinking-water supplies by a simple kind of local inspection and by education. Wells must be located with great care. The considerable distance to which bacteria may travel in ordinary soil in the direction of the ground water flow—*but not against it*—has been beautifully shown by Mrs. Elfreda L. Caldwell in experiments conducted under the guidance of Dr. F. F. Russell, Director of the International Health Division of the Rockefeller Foundation. The danger of contamination of the wells and the treacherous springs in limestone regions with their numerous underground water channels is, of course, peculiarly acute. State boards of health serving rural communities are in a position to prevent much typhoid at small expense through competent inspection of the water supplies in small towns and country districts. No longer do the large cities act as typhoid foci from which the disease spreads throughout the surrounding territory. In many localities the majority of the typhoid patients in city hospitals are not city residents but are imported from the neighboring suburban or rural population. The chief reason for this shifting of typhoid incidence from the large population groups to the small ones is

the superior urban control exercised over drinking water.

Thirty years ago raw milk was probably second only to water supply as a vehicle of typhoid infection in the United States. There is no need to dwell on this fact or on the change that has occurred. The general introduction of the process of pasteurization has all but eliminated milk-borne typhoid in the larger urban centers. To be sure, the extraordinary Montreal outbreak of 1927 is still fresh in our minds, but every one will agree that the conditions permitting that outbreak and its long continuance were in the highest degree exceptional. The value of pasteurization in preventing not only typhoid but a number of other diseases is too well recognized to need special exposition.

As regards milk supply also, the smaller communities are at a disadvantage. Properly pasteurized milk is less easily come by in small towns and villages than in cities, partly for financial reasons connected with the existence of a relatively large number of small milk supplies. It would seem probable that improvement might be effected through some form of unification, but I am aware that this is a difficult and delicate problem. It is encouraging to note that the practicability of municipal pasteurization plants for small towns is being discussed with a view to some form of organization making it possible for distributors to exchange at a central plant their raw milk for pasteurized milk each day, going on to deliver the bottled pasteurized milk to their customers. The use of federal loan funds for the construction of such small plants has been suggested.

As is well known, other raw foods besides milk may sometimes be vehicles of typhoid infection. Vegetables commonly eaten without cooking, such as celery, watercress and lettuce, have been occasionally incriminated; raw oysters,

mussels, and clams have caused typhoid in a number of instances. These sources of typhoid are susceptible of control. Great improvement in sanitary measures in the oyster industry have been made in recent years. Contamination of vegetables may be almost wholly prevented by the avoidance of the use of human excrement for fertilizing truck gardens.

A far more important aspect of food-borne typhoid infection is the contamination of food by typhoid carriers in the kitchen or on the way to the table. Some have proposed to remedy this by bacterial examination of all food handlers in dairies, bakeries, lunch counters, hotels, restaurants, and boarding houses. Apart from the colossal amount of labor and expense involved in routine examination of numbers running into the tens of thousands in our larger cities and including a rapidly changing personnel, there are certain technical difficulties that make such examination of doubtful practical value. Chief is the well known intermittency of discharge of typhoid bacilli so that a single failure to find typhoid bacilli in the stools of a food handler, and even several consecutive negative results, give no guarantee of safety. Cultures from the bile sometimes give positive results when stool cultures have been negative. In some instances carriers who have been proved to transmit infection, discharge typhoid bacilli only at long intervals over a term of years.¹

Detection of carriers by bacterial examination has thus far been most valuable in connection with specifically identified sources. There is abundant evidence that in communities where water-borne and milk-borne infection have been practically eliminated, it is carrier infection that keeps the disease alive. Milk-borne infection itself is mainly a problem of carriers. An instance is on record where one and the same carrier apparently gave rise to

typhoid in three different ways, by milk, by contact, and by water contamination.²

The effective control of known typhoid carriers is well recognized as a vexatious problem in public health administration. It is a serious matter to take away a family's means for livelihood, or to cause an individual to be looked upon as an outcast by neighbors and friends. Too great severity in supervision may lead simply to shifting the carrier's field of operations. On the other hand, there are unquestionably some cases where indefinite detention of a carrier in a hospital is necessary to protect the public health; this is recognized in the recent revision of the Sanitary Code of the City of New York.

Attempts to cure typhoid carriers by non-surgical means, such as chemotherapy, vaccine therapy, or bacteriophage, have not been generally successful and number few advocates at the present time. Surgical treatment, especially removal of the gall-bladder, has much to recommend it. In a series of 12 cases recently reported by Bigelow and Anderson,³ removal of the gall-bladder was apparently followed by complete cure of the carrier condition. In another series studied in New York State removal of the gall-bladder re-

sulted in the apparent cure of the carrier condition in 59 per cent of those from whom required specimens had been submitted. There were no fatalities in 35 carriers who were under 50 years of age at the time of operation, but the mortality in those over 50 was 32.3 per cent.⁴ Browning and his coworkers in England⁵ have also reached the conclusion that removal of the gall-bladder yields highly satisfactory results. The risks of operation *for persons of suitable age and physical condition* seem to be justified since chronic infections of the gall-bladder are likely sooner or later to affect seriously the health of the carriers. From the standpoint of efficiency and administrative economy this method of dealing with carriers is probably superior to any other.

While the number of registered carriers is a relatively small proportion of the total—in Massachusetts 75 known carriers out of a calculated 1,100 in the state—there is no reason to assume that the undiscovered carriers are equal sources of danger. Some of them undoubtedly never give rise to a single case of typhoid.

It must be remembered also that the carrier problem is in a sense solving itself, that all preventive measures

TABLE I
AGE GROUPS OF TYPHOID CARRIERS

automatically reduce the number of carriers. Any decrease in typhoid is cumulatively as well as immediately beneficial. The typhoid carrier is passing off the stage.

Available figures give some evidence of this. I have tabulated (Table I) the age distribution of 220 carriers studied in the first decade of this century during the campaign against typhoid in the southwest of Germany together with that of 368 carriers discovered in New York State (not including New York City) between 1911 and July 1, 1932, nearly all of them in the last 10 years. This comparison (Table I) shows that in 1906-1907 there were many more carriers under 50 years of age than over, while in recent years the reverse is true.

Closely connected with carrier infection is the possibility of infection directly or indirectly from typhoid patients. Although this danger is well known, and nurses and physicians are as a rule measurably protected by vaccination, there is evidence that infection—what used to be called “contact infection”—from this source should be carefully guarded against. Such infection may be easily carried outside the family. In April, 1933, 11 cases with 2 deaths were caused among those attending a church supper in an Illinois town through food contaminated by a mother who had been nursing her son, ill with supposed “intestinal flu,” later diagnosed as typhoid. There is no doubt that medical students in large urban centers no longer have a chance to become thoroughly familiar with clinical typhoid and that occasional mistaken diagnoses are not unlikely. Suspected typhoid, as well as diagnosed typhoid, should be at once reported to health authorities.

The responsibility of hospital management in typhoid fever cases is a grave one. So far as I am aware there are no data that indicate how far this responsibility is met, but it must be

borne in mind that, as Garbat⁶ has shown, the usual routine stool examinations during convalescence may miss 15 per cent of all typhoid carriers, and that 25 per cent of the temporary carriers alone may be dangerous for as long as from 1 to 2 months after defervescence. The infective status of the typhoid patient on his release from the hospital is, therefore, a matter of serious concern to health officials.

Improper disposal of excretal refuse has almost disappeared as an urban problem, and is less urgent than it used to be in country districts as a result of the campaign for sanitary privies. The importance of guarding against transmission of infection by house flies or vermin having access to imperfectly constructed privies has received wide publicity. In certain sections of the country, however, much still remains to be accomplished. The remarkable success that has attended the installation of proper sanitation throughout the island of Jamaica under unusually difficult climatic and economic conditions may well spur us to new efforts in this field.

Prophylactic inoculation against typhoid, as all the world knows, has been brilliantly successful in preventing extensive infection among soldiers and others specially exposed. Its use should be mandatory in asylums and all custodial institutions. All persons exposed by their mode of life, such as physicians, nurses, medical students, laboratory workers, laborers in lumber or construction camps, and travelers in typhoid-ridden countries, should be inoculated against typhoid as a routine practice. Although the protection so conferred is by no means absolute and is known to have been broken down in a number of instances, probably by massive doses of infection, the evidence from comparative statistics is overwhelmingly favorable.

With regard to widespread inocula-

tion of civilian populations, we need more evidence as to the types of vaccines used, and especially do we need full and adequately controlled records before we are in a position to determine the relative value of this procedure as compared with that of more fundamental measures. The recent work of Grinnell⁷ on the relative ineffectiveness of the Rawlings typhoid strain as an immunizing agent has been confirmed by Perry and his associates⁸ who found that 10 unvaccinated mice all died with the test dose of a virulent typhoid strain, and that 28 died out of 30 mice vaccinated with three different vaccines prepared from the Rawlings strain, whereas only 3 died out of 27 mice that had been vaccinated similarly with a demonstrated smooth strain recently isolated. While caution of course is necessary in applying the results of such experiments to man, there is abundant reason for knowing definitely about the character of the vaccine before embarking upon vaccination "campaigns." Conceivably there are conditions where general civilian vaccination may be hopefully undertaken, but we need more evidence as to its real value. Unless control is exercised in a given area over water supply, excreta disposal, and other well known factors, the results from wholesale

vaccination may be disappointing. If these basic sanitary measures are properly carried out, general vaccination may be unnecessary. It is better to put the house in order than to wallow in dirt and then take medicines to ward off the effect of slovenly living.

The general strategy of combating typhoid fever at the present time seems clear. It consists essentially in putting into practice the knowledge we already possess. First, tighten and strengthen the barriers that prevent typhoid bacilli from getting into drinking water or into milk and other foods. Second, in those communities where typhoid has already been reduced to a low point by the application of such measures, investigate the source of each case and minor outbreak and concentrate on the elimination of case infection, and especially carrier infection, knowing that time itself is fighting on our side.

What Are the Essentials of Typhoid Fever Control Today?*

GEORGE H. RAMSEY, M.D., DR.P.H., F.A.P.H.A

*Director, Division of Communicable Diseases, State Department of Health,
Albany, N. Y.*

THE question "What are the essentials of typhoid fever control today?" carries with it the implication that these essentials are no longer the same as formerly. Although our fundamental conceptions as to the cause and mode of transmission of typhoid fever remain the same, the problem of control is materially different from that of a generation or even a decade ago because of the changes which have taken place in the prevalence of the disease. Since these changes have a direct relationship to prevention, they will be discussed briefly before reviewing the present status of typhoid control.

TYPHOID PREVALENCE

The trend of typhoid mortality during the past 20 years in 11 states, 6 of them in the northern, and 5 in the southern part of the country, is shown in Table I and in the accompanying graph. The northern states are Connecticut, New Hampshire, Maine, Michigan, Minnesota, and Wisconsin, and the southern states include Kentucky, Maryland, North Carolina, Tennessee, and Virginia.* Populations and deaths for places of less than 10,000 population in North Carolina in 1913, and for the State of Tennessee from 1913 to 1916 inclusive, are not

included because data for these areas in the years specified are lacking.

The typhoid death rate in the 11 states fell from 21.9 in 1913, to 4.2 in 1932, a decline of 81 per cent. Similar decreases have been observed throughout the United States and Canada (Howard 1932, *Mon. Epi. Rept. League of Nations, 1933*), and although the term "residual typhoid fever" was in common use 20 years ago, there is little indication that death rates in most states and provinces have ceased to decline or have yet approached stationary levels.

That the downward trend of typhoid mortality has been general, and not limited to any one section of the country or population group, is demonstrated by Table II. In this table are given urban and rural typhoid death rates by 5-year periods from 1913 to 1932 inclusive among the white populations of the 5 southern states, and among the total populations of the 6 northern states previously mentioned. Rates among the white populations of southern states are compared with rates among the total populations of northern states because of the low proportion of negroes

* Read before a Joint Session of the Health Officers, Laboratory, and Epidemiology Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

* According to the 1930 Census, the 6 northern states had a combined population of 13,214,903 persons, and the 5 southern states a combined population of 12,454,798 persons. The density of population for northern states was 56 persons per sq. mi. and that for southern states 69 persons per sq. mi. Fifty-nine per cent of the population of northern states, and 34 per cent of the population of southern states lived in places with 2,500 or more inhabitants in 1930.

TABLE I
TYPHOID FEVER DEATH RATES IN 11 STATES, 1913 TO 1932, INCLUSIVE *

Year	Population	Number of deaths	Death rate per 100,000
1913	16,087,910	3,529	21.9
1914	18,510,750	3,706	20.0
1915	18,784,056	3,159	16.8
1916	19,057,362	3,208	16.8
1917	21,629,131	4,008	18.5
1918	21,918,207	3,222	14.7
1919	22,197,286	2,820	12.7
1920	22,513,653	2,192	9.7
1921	22,837,352	2,681	11.7
1922	23,161,049	2,066	8.9
1923	23,484,746	2,019	8.6
1924	23,808,443	1,888	7.9
1925	24,132,142	2,388	9.9
1926	24,455,838	2,019	8.3
1927	24,779,537	1,696	6.8
1928	25,103,233	1,360	5.4
1929	25,426,932	1,170	4.6
1930	25,750,626	1,343	5.2
1931	26,074,322	1,262	4.8
1932	26,398,018	1,115	4.2

* States included: Connecticut, Kentucky, Maine, Maryland, Michigan, Minnesota, New Hampshire, Virginia, Wisconsin 1913-1932; North Carolina 1914-1932; Tennessee 1917-1932.

in the North. The terms "urban" and "rural" are here used as in *U. S. Mortality Statistics* where places with less than 10,000 population are classified as rural.

Table II shows marked decreases in the urban and rural sections of both northern and southern states. These decreases have been more extensive, and the final rates are considerably lower in the North than in the South. However, although lagging behind northern ratios, the rates in southern states are more than two-thirds lower than they were, the white urban rate in the South having declined 77 per cent, and the rural rate 68 per cent during the 20-year period.

Moreover, typhoid fever mortality has decreased to a remarkable extent even in the smallest and most scattered population groups. Thus, the mean annual typhoid death rate (based on

deaths allocated to place of residence) for New York State unincorporated territory from 1913 to 1917 inclusive was 8.0, and the corresponding rate for the same population group from 1928 to 1932 inclusive was 1.5 per 100,000. This decline of 81 per cent is noteworthy since it occurred for the most part in strictly rural districts without public water supplies, and in New York, a state where only a negligible proportion of the population have received typhoid vaccine.

According to a compilation of communicable disease cases made by the U. S. Public Health Service for the White House Conference (1931), the trend of typhoid morbidity has been the same as that of mortality. Taking both morbidity and mortality data into consideration, it appears that, by and large, typhoid fever has decreased in prevalence more than any other common

acute communicable disease with the possible exception of diphtheria. The extent and continuance of this decline have been stressed for two reasons, one of which is to point out that due caution must be exercised in evaluating the results of preventive measures by means of reductions in morbidity and mortality rates. Typhoid case and death rates are falling so rapidly that reductions in a given area cannot be interpreted as directly resulting from any single preventive measure, unless they are significantly greater than those in similar localities where the same measure has not been employed.

A more important reason for emphasizing changes in typhoid prevalence is to make it clear that control of the disease is no longer the object to be attained. Provided decreases can be made

to continue at their present satisfactory rate, the complete eradication of typhoid fever is an actual possibility, and is the goal toward which future preventive efforts should be directed.

ENVIRONMENTAL PREVENTIVE MEASURES

That our present favorable typhoid situation has been arrived at largely because improvements in water, and milk supplies, sewage disposal facilities, and other environmental conditions is seldom, if ever, seriously questioned. Certain recent studies afford confirmatory evidence of the association between environmental factors and typhoid prevalence, and serve to demonstrate that the possibilities for further reductions by means of sanitary improvements have not yet been exhausted.

TABLE II

MEAN ANNUAL URBAN AND RURAL TYPHOID FEVER DEATH RATES PER 100,000 IN 6 NORTHERN STATES, AND AMONG THE WHITE POPULATIONS OF 5 SOUTHERN STATES, BY 5-YEAR PERIODS, 1913-1932 INCLUSIVE *

DEATH RATES PER 100,000

Period	Urban		Rural	
	Southern white	Northern	Southern white	Northern
1913-1917	20.8	12.8	27.8	7.5
1918-1922	10.6	5.7	17.6	4.4
1923-1927	6.8	3.0	14.0	2.2
1928-1932	4.7	1.2	8.8	1.3
Per cent decrease	77	91	68	83

* Data 1913-1929 inclusive from U.S. Mortality Statistics
Data 1930-1932 obtained from States by correspondence

Veldee (1931) found that in 6 Ohio river cities typhoid death rates were somewhat reduced by changes from raw water to partially treated supplies, but were not brought down to rates comparable with those in a control group of cities until the water supplies received entirely adequate treatment. It is probable that reductions of the same sort have followed successive water supply improvements in cities generally, these reductions being less striking than those in earlier years, and therefore less commented upon. A large number of New York State water supplies have been improved during the past two decades, particularly in villages and cities of from 2,500 to 25,000 population, the majority of larger cities having had good or fairly good supplies prior to 1913. From 1913 to 1922 inclusive, 24 water-borne epidemics are known to have occurred in the 138 places belonging to the 2,500 to 25,000 population group, whereas during the period 1923 to 1932 inclusive, there were only 6 water-borne outbreaks in places of the

same size, no such outbreaks having occurred since 1928. In 1,301 communities with less than 2,500 inhabitants, and with proportionately fewer water supply improvements, there were 14 water-borne outbreaks from 1913 to 1922, and 10 water-borne outbreaks from 1923 to 1932 inclusive.

Doull, Morales, and Haygood (1928) found that in Knoxville, Tenn., typhoid fever was most prevalent among persons who, though living inside the city limits, used privies or outdoor flush closets, and drank water from wells and springs. It is believed that if this survey were repeated in other cities with high typhoid death rates, similar results would be obtained, and that in spite of accessible city water supplies and sewerage systems, large numbers of people drinking spring or well water and using privies would be found.

After an intensive study of recent epidemics, Wolman (1931) gave warning that water-borne typhoid fever is still a menace, and emphasized the necessity for continued efforts to improve the

quality and supervision of water supplies. The same statement should be made with respect to milk supplies, sewage disposal facilities, and other environmental conditions. Environmental preventive measures are still major essentials of typhoid control, and it is certain that these measures have not yet been used to the fullest possible extent, especially in areas where the prevalence of the disease remains strikingly high.

TYPHOID CARRIERS

With the gradual elimination of opportunities for the wide dissemination of the disease by means of polluted water and milk supplies, and other defective environmental factors, typhoid carriers have come into greater and greater prominence, and as sources of infection now occupy, or should occupy, an important place in control programs. The vast majority of carriers are discovered either during investigations of typhoid cases and outbreaks, or as the result of requiring release specimens of feces from convalescent patients.

As regards the discovery of carriers by means of epidemiological investigation, it is clear that success depends upon careful, intelligent case study by qualified personnel. Unfortunately, the ideal of tracing the majority of sporadic cases, and small endemic typhoid foci to carrier infection is scarcely ever realized even in states with the fewest cases and best investigative facilities. Reasons for failure include superficial inquiry as to the circumstances surrounding the case, lack of sufficient numbers of fecal specimens from contacts and suspected carriers, and in some instances poor laboratory examination of the specimens obtained.

As would be expected, more carriers have been discovered in New York State by means of epidemiological investigation in small communities than in large cities. Two-thirds, or 194 of

the 288 carriers so discovered in the state, outside of New York City and state institutions, up to the end of 1932 were found in villages of less than 2,500 population or in unincorporated territory.

Excluding all those in known epidemics, 1,354 typhoid cases were reported in New York State places with more than 2,500 population outside of New York City and state institutions from 1928 to 1932, inclusive. During the same period, 1,325 non-epidemic cases were reported in places of less than 2,500 population and unincorporated territory. Thirty-five carriers were discovered from 1928 to 1932 inclusive, in the investigation of non-epidemic cases in places of more than 2,500 population, and 65 carriers were discovered in places of less than 2,500 population and unincorporated territory by means of the investigation of cases not occurring in outbreaks. Thus, a carrier was discovered for every 20 sporadic cases in places of less than 2,500 population and unincorporated territory, whereas the ratio of non-epidemic cases to carriers epidemiologically discovered in places with more than 2,500 population was 39 to 1.

Since this control measure has been used in New York State, 88 typhoid carriers have been added to the register as a result of making the release of convalescent patients conditional upon the submission of negative fecal specimens. Records have been kept since January 1, 1930, showing the number of fecal specimens obtained from each case, and the results of each examination. Between January 1, 1930, and September 1, 1932, complete records for 1,599 cases were obtained. Of this group of patients, 191 died, and 43 absconded or left the state. Two or more fecal specimens were obtained at intervals of at least 5 days and 3 weeks or more after date of onset from all but 47 of the remaining patients. Thirty-three,

or 2.5 per cent, of these 1,318 individuals remained positive for typhoid bacilli and have been, or will be declared carriers, this proportion being almost identical with that for Massachusetts reported by Bigelow and Anderson (1933).

Methods for supervising typhoid carriers, and the results of gall bladder operations for their cure have recently been described by Senftner and Coughlin (1933), and Bigelow and Anderson (1933). A few states and cities already have well developed facilities for handling the typhoid carrier problem; but looking toward the eradication of the disease there is great need for the extension of this service in all parts of the country. Granting that the administrative machinery for these purposes is of necessity cumbersome, the discovery and supervision of carriers are essential preventive measures, not to be neglected because of the difficulties incident to carrying them out.

INDIVIDUAL CASES AND CONTACTS

At the present time, some communities go through an entire year without a single typhoid case and, excluding epidemics, there are few cities and counties in which more than 75 or 100 cases are reported annually. Typhoid fever now belongs to the group of uncommon diseases, demanding confirmation of diagnosis, and active health department participation in the management of each individual case.

The dearth of typhoid cases in teaching hospitals has been mentioned on various occasions, and since clinicians in practice see cases rather seldom, other febrile conditions, notably tuberculosis and undulant fever, are not infrequently erroneously diagnosed typhoid fever. Of the 3,561 typhoid and paratyphoid cases reported in New York State, outside of New York City, from 1928 to 1932 inclusive, 114 were

later removed from the register because of wrong diagnosis. This number takes into account only cases in which the clinician went so far as to commit himself definitely to the local health officer, there having been an unknown but probably considerable number of instances where the diagnosis was changed before a report card had been filled out.

The advantages to the typhoid patient of hospital care have long been realized. Certain data are now available suggesting that the hospitalization of cases is also of value as a means for preventing the occurrence of subsequent cases among household contacts.

According to New York State records for the years 1930 to 1932 inclusive, in families where the primary case was hospitalized, 85 subsequent typhoid cases occurred among the 1,221 household contacts who had not been immunized or had typhoid fever previously, the subsequent attack rate being 7.0 per cent. Of 1,035 contacts of similar status with respect to previous attacks and immunization, but who lived where the primary case remained at home, 110, or 10.6 per cent, were attacked. Thus, the incidence of subsequent cases was more than a third lower when the primary case was hospitalized than would have been expected if this patient had remained at home.

Further, considering individual patients and members of the same families, it is possible to show indirectly that the incidence of secondary cases is related to the environmental status of the household. Subsequent attack rates among familial contacts of typhoid patients in places of 10,000 and over, and in places of less than 10,000 population in New York State, exclusive of New York City, are presented in Table III, the incidence of secondary cases being shown for two periods, namely, during the first 14 days after the onset of the primary case, and 15 or more days after this. In the preparation of this table,

all cases and contacts in known epidemics have been omitted; cases and contacts in families where a known carrier existed prior to the date of onset of the initial case have also been omitted; contacts giving histories of typhoid vaccination or previous attacks of typhoid fever have been left out.

The subsequent attack rates in both periods were significantly higher in places with less than 10,000 population, than in places with more than 10,000 inhabitants. Some of the cases during the first 14 days may not have been secondary, but may have arisen from the same source as the primary case. However, few original sources would be expected 15 or more days after the primary case, so that most of the cases in the latter period were probably contracted as the result of familial exposure.

Household contacts in communities of 10,000 or more population were apparently exposed to less risk than contacts in smaller communities. This finding may be interpreted as being due to the fact that houses in places of

10,000 or more population are generally equipped with running water and indoor flush closets, conditions under which the observance of case prophylaxis would be much easier than in homes without such conveniences.

TYPHOID VACCINATION

Of the preventive measures which have been widely used, vaccination remains to be considered. There is no doubt as to the efficacy of this procedure as a method for protecting contacts and individuals apt to be unduly exposed by reason of occupation or travel, and its usefulness as an emergency measure in civil population groups has likewise been proved. For example, Mustard (1930) reported the occurrence in Rutherford Co., Tenn., of 29 secondary typhoid cases among 695 non-immunized household contacts, but observed no secondary cases among 776 household contacts who had been immunized 1 month or more prior to exposure.

Although of demonstrable worth under special and emergency conditions,

TABLE III

SUBSEQUENT ATTACK RATES FROM TYPHOID FEVER AMONG CONTACTS IN FAMILIES WHERE THE PRIMARY CASE REMAINED AT HOME, ACCORDING TO LOCALITY AND DATE OF ONSET OF PRIMARY CASE, NEW YORK STATE, 1930-1932, INCLUSIVE *

Size of Locality	Days after onset of primary case				Subsequent attack rates per cent	
	1-14		15 and over		Days after onset of primary case	
	Number exposed	Number of subsequent cases	Number exposed	Number of subsequent cases	1-14	15 and over
10,000 and over	290	8	282	4	2.8	1.4
Under 10,000 and unincorporated territory	557	41	516	29	7.4	5.6
Total	847	49	798	33	5.8	4.1

* Exclusive of New York City and State Institutions, and exclusive of cases and contacts in known epidemics; contacts with histories of vaccination and previous attacks; cases and contacts in families with known carriers.

there are valid objections to the vaccination of civil population groups as a permanent, or semi-permanent control measure. In the first place, the argument used in advocating smallpox and diphtheria immunization as permanent measures to the effect that infection may be acquired from hidden sources even when there are no known cases in the community does not hold in typhoid fever. Unlike the other two diseases, sources of infection in typhoid fever are more or less stationary in character, and of such a nature they can eventually be eliminated.

The highest typhoid death rate observed during the period 1928 to 1932 inclusive, in any population group in the 11 states previously mentioned, was that for negroes in the rural sections of southern states, among whom deaths occurred at a rate of 13.4 per 100,000. At this expectancy, it would be necessary to immunize 7,400 people to prevent a single death, and about 740 people to prevent a single typhoid case. Taking into consideration the brief duration of the protection conferred by typhoid vaccine, the wisdom of spending time and money on a procedure which gives promise of such meager results may well be questioned.

SUMMARY

Typhoid fever has decreased in prevalence to a remarkable extent in all sections of the country, even during very recent years. Because of the low levels already reached, and since typhoid case and death rates are continuing to fall rapidly, eradication of the disease rather than control is the goal toward which future efforts should be directed.

Examining various preventive measures with the possibility of typhoid eradication in

mind, it has been concluded that measures for the improvement of environmental sanitation are of major importance, and that these measures have not yet been used to the fullest possible extent.

Among the preventive measures which have come into greater prominence with the decline of the disease are procedures for the discovery and supervision of typhoid carriers. There is great need throughout all sections of this country and Canada for more intensive case investigation, and for the development of facilities for the supervision of carriers.

Typhoid fever now belongs to the group of rather uncommon diseases in which the diagnosis must be confirmed and the health officer must participate in the management of individual cases. It appears that other members of the household are less apt to contract typhoid fever when the primary case is removed to a hospital, and that when the patient remains at home fewer secondary cases occur in large than in small communities.

Under special and emergency conditions, typhoid vaccination is a useful and necessary procedure, but its employment as a permanent control measure in civil population groups is of doubtful value.

Modern Trends in Public Health Administration in Cities*

JOHN P. KOEHLER, M.D., F.A.P.H.A.
Commissioner of Health, Milwaukee, Wis.

PRESENT trends in public health administration, in cities, are essentially the same as are those in counties and states. This is what one might expect, since some of the more important reasons for certain trends are the same throughout the country. I shall not attempt to mention changes that are occurring in many cities due primarily to the many various local conditions, but shall limit my discussion mostly to changes or trends that are more or less common to all cities.

It is generally acknowledged that business concerns should periodically take an inventory of their stock in order to plan intelligently for the future. During normal or prosperous times, it may be safe to drift along without worrying very much about one's present position or future destination, but during the storms of an economic depression, it behooves everyone to keep his eye on the compass and his hand on the helm.

What is true of business is also true of public health work. The time has arrived when even health officers must stop and ask: "Where are we heading?" The days of fairly adequate appropriations and sympathetic support for public health work are only pleasant memories in most communities. Many of the public health activities have been put in the class of nonessential public

services in many cities, instead of being considered at least as vital to the welfare of a city as are fire and police protection and education. Reducing health department budgets even during normal times is a serious matter, but reducing them during years of poverty and distress, when both the need and the demand for public health services are tremendously increased, is something that even the most pessimistic health officer did not expect. The demand of tax payers for more and better public health service at a lower cost, has forced health officers to make many changes, regardless of the merits of such changes.

In considering, therefore, modern trends in public health administration, it must be remembered that many of such trends are apt to be only temporary, because they are due more to restricted budgets than to intelligent and efficient planning. There are some, however, that are not related to the present economic depression, and for that reason may be considered both permanent and desirable.

According to reports, which 20 city health officers were good enough to give me, some of the present trends in public health practice are as follows:

First, a more efficient and conscientious appraisal of all health activities and the elimination of the less essential services. One health officer expresses this trend as follows:

The keynote of administration is to fight to the last ditch for the retention of essential

* Read before the Health Officers Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

health services, and to permit the less essential things and all the frills to go by the board.

There appears to be no agreement as to what the less essential or so-called frills are. Most cities have reduced their appropriations for health bulletins, annual reports, and other health publications, but one health officer writes:

It is very unfortunate that a great number of health departments have ceased to publish their bulletins and have curtailed their annual reports. This so-called depression has brought about economy which spells ruin for the proper steady development of health departments.

Fortunately, the inexpensive practice by health officers of making more use of the daily newspapers, the platform, and radio will at least to some extent make the curtailment of health department publications less serious.

Many cities have curtailed their school hygiene programs, by materially reducing the number of physical examinations of school children, but no one will contend that such examinations, even when hurriedly made, can be put in the class with frills. While it is true that some health services may appear nonessential when compared with other very vital health activities, nevertheless, when compared with road construction and reforestation programs, the development of public parks and playgrounds, the construction of water power and irrigation projects, and many other expensive public undertakings, they not only appear very valuable, but also ridiculously inexpensive. On the whole, health departments have had to fight too hard for increased appropriations, even during prosperous times, for them to have been even tempted to develop so-called frills. Almost every public health activity is considered unnecessary by the large tax payers who have all at once discovered that it is cheaper for them to purchase their preventive treatment from the private physician, than to be taxed for a community health pro-

gram. Let us, therefore, be very careful in appraising our present health services, and not be influenced too much by selfish interests.

The second trend that seems to permeate nearly all city health departments is toward coördination and consolidation. Various divisions within health departments are being merged into larger units. It is becoming more common to consolidate the divisions of contagious disease, tuberculosis, and venereal disease into one bureau or department.

The trend from specialized public health nursing to generalized nursing is slowly continuing.

Better team work is being developed between public health departments and private health and social agencies.

Cities are depending more on general hospitals for the hospitalization of contagious disease cases.

The tendency to transfer services related to public health, but not necessarily requiring health department supervision, to other city departments, is on the increase. It is being realized more and more that activities related to public hygiene and sanitation can be supervised more economically and much more efficiently by the police, fire, public works, and housing departments, than by a few sanitary inspectors.

In many cities health departments have been compelled to assume responsibility for the treatment of the indigent sick. The demand for free medical care has become so great that it can no longer be met by the medical profession and small private dispensaries.

At least one health department is also offering free diagnostic service to private physicians for patients unable to pay the fees of specialists. There is a great need for this type of service and unless the medical profession offers better diagnostic service to the middle class people, the trend toward a public diagnostic service will grow.

Although the demand for economy has forced many mergers in health departments and communities, yet few, if any, mergers of several communities have occurred. Politicians still prefer expensive and inadequate public service to the danger of losing their jobs through the consolidation of several governmental units.

As a third trend, I might mention the increasing practice of health departments to center their attack on younger age groups. Diphtheria immunization work is gradually being limited to infants and preschool children.

In tuberculosis work health departments are no longer waiting for people, with a history or signs and symptoms of tuberculosis, to report to their chest clinics for an early diagnosis, but are developing intensive tuberculosis detection programs in schools. The tuberculin test and X-ray are no longer limited to a few children suspected of tuberculosis, but are made available in many cities to all children in the upper grades and high schools.

The last, and undoubtedly the most important trend in public health administrative practice, is the turning over to the medical profession of many old established health services. Most of these were established in health departments years ago by physicians in private practice. At that time it was felt by members of the medical profession that a preventive health program could only be successfully developed and operated by a public health agency.

For years, health departments with the coöperation of private physicians have gradually enlarged and improved their health activities. Very few physicians questioned either the authority or ability of health departments to conduct child welfare, tuberculosis, venereal disease, and immunization clinics, until recently.

Not only are private physicians demanding a greater opportunity to participate in preventive health work, but nearly all health officers are willing to turn over at least some of their work to private physicians. Whether this is only a temporary trend due to the economic depression, or a permanent change, is not easy to determine. I feel certain, however, that unless this change in public health practice is made in an orderly, unselfish, and intelligent manner, there is great danger that everyone concerned will sooner or later suffer from an inadequate and impractical public health program.

The following excerpts taken from letters of health officers, give perhaps a fair picture of the attitude prevailing among health officers on this problem:

1. The private physician should be given a more recognized place in the health of the community.

2. Find some means to overcome the antagonism of private physicians to the preventive work we are trying to do.

3. My views with respect to present trend generally in cities in public health work, are that while many of the activities undertaken by government agencies in various cities probably accomplish a good purpose and meet the approval of the citizens generally, I am wondering on the other hand, if many of these activities do not legitimately belong to the private physician, and should they not be given proper consideration.

4. I realize that in some of the larger centers, the medical profession has interested itself considerably in the advancement of public health work. I cannot believe that this will become permanent, or that it will assume the responsibility of carrying on public health work. A few of them, undoubtedly, would show sufficient interest and take the responsibility, but not the rank and file.

5. After many years of public health work, I still feel that the sum of the efforts of the individual physicians is the greatest asset in the whole game of public health. Any health officer who has not the full confidence of the medical profession is a failure and his work is a failure.

6. I should like to feel that the trend is toward preventive medicine among both the medical profession and the laity, but I am

afraid this would be limited to a comparatively small group.

7. We are continually dodging thrusts from various organizations, even sometimes from our own profession, and we have got to work out some problems of our own organization in order to make ourselves secure.

8. Now as to tendencies for the future no one can prognosticate with certainty. My own impression, formed from personal observation of what is going on around me, and from reading about what is transpiring in other provinces of the Dominion as well as in the United States, is that we are gradually coming to State Medicine, whether we like the prospect or the reverse. Legislation in the Western Provinces providing for the appointment of government paid district physicians and the increasing army of private physicians, earning barely a decent subsistence, that in increasing numbers are openly advocating State Medicine as a solution for present difficulties, would indicate a trend in its favor on the part of both the profession and the laity.

The adoption by states and provinces of the responsibility for providing an adequate medical service for the vast population comprising what might be called the near indigent, presupposes changes and adjustments in our public health services, local, state, and federal, which it would be entirely impossible to predict. Moreover, in my opinion, it can be reasonably contended that hospital administration in many of its aspects is and should be intimately related to the public health program of the community, and the same is true in regard to the administration of poor relief.

Briefly expressed, it is my firm opinion that we are approaching a new era—a new conception of values in the field of preventive medicine—and that if we are to justify our work in the future new relationships and adjustments in the fields of prevention, therapeutics, social service, hospital administration, voluntary assistance, etc. will eventually be adopted.

We see from these excerpts that even health officers do not agree among themselves as to certain trends and their merits. It appears that the time has arrived when a public health program should be developed to which not only all health officers can conscientiously subscribe, but which will also be approved by the medical profession.

Representatives of the American Pub-

lic Health Association ought to meet the representatives of the American Medical Association, to see if it is not possible to standardize a public health program, satisfactory to both organizations, without in any way jeopardizing the health and welfare of the public.

While someone has said that variety is the spice of life, we do not want to make radical changes in public health practice merely to be changing. During economic depressions when people are compelled to give up many things which they have previously enjoyed, we find irresistible demands for all kinds of changes. Many of the demands are spontaneous, justifiable, and for the benefit of society, while others are forced by a selfish minority, are unreasonable, and are very apt to be detrimental to a majority of the people.

The philosophy that when things are very bad they cannot be made worse by any kind of a change, has been responsible for much grief and regret in the past, and should therefore be applied very cautiously in the future. It may be safe to change our local, state, or national administration during a period of economic depression and unrest; it may even be safe to change our constitution and long established governmental policies; in fact, it is not only safe to make changes in our political, economic, financial, and social life, but such changes are absolutely necessary, if civilization is to continue. The changes we must guard against are those that would have us give up something that has proved its value over a period of years, for something that is still in the experimental stage. Public health work, as practised during the last two decades, has stood the severe test of a 4-year economic depression, which should make all of us hesitate to accept radical changes without conscientious, fearless, and intelligent consideration.

The Depression and Its Effect on the Mental Health of the Child*

HENRY C. SCHUMACHER, M.D.

*Director, Child Guidance Clinic; Associate Professor of Mental Hygiene,
School of Applied Social Sciences, Western Reserve University,
Cleveland, Ohio*

THERE is probably no other single factor, unless it be the innate constitutional make-up of the child, which is so important in determining personality traits and life attitudes as the familial relationships in which the individual finds himself. The significance of such relationships is not to be understood primarily in terms of blood relationship or kinship but must be found in the personal interactions of the different members comprising the family. It quite naturally follows, therefore, that in any discussion of the depression in relation to mental health of the child we cannot ignore the effect of the depression on all the members of the family and, by extension of these effects since no family lives solely unto itself, on all others with whom the child comes into close contact such as teachers and playmates.

It is unfortunately true that the effects cannot be measured statistically in a satisfactory manner. In fact, what follows in this paper is pretty much the impressions of the writer drawn chiefly from his rather intimate contact with social agencies and as the direct result of his work in the Cleveland Child Guidance Clinic. Quotations from the writings of others will

be cited only to substantiate the writer's own impression.

Let us cite what in the records of family and relief agencies is a very common story. Every psychiatrist in child guidance work is all too familiar with it. It will serve as a bird's-eye sketch of what is to follow.

In the early days of the depression Mr. A., a sub-executive, like many other Americans in high and low places, did not take the situation so seriously. The attitude then expressed was that it could not last long, good times were just around the corner. As the months wore on and spring came without bringing improvement this seeming indifference was put aside. Husband and wife were plainly worried. The man was tramping the streets from morning till night but without success—a job could not be found. Mrs. A., however, could not understand the situation. She felt the husband was not really looking for work. Then began the family quarreling. The children quite naturally took sides—the boys were apt to side with mother, the girls, always close to their father, thought mother unfair to him.

Retrenchment had been made all winter. By spring, the savings were well-nigh exhausted. Standards of living were being lowered. It became necessary to give up their home and move into cheaper quarters in another

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

section of the city. The children were transferred from private school to public school. Their little world came toppling down about them and there was nobody to help interpret it to them. For them it spelled disaster. Their lives had been lived on another level. The question is not whether that was the proper level but rather that on that level they had been reared. They lost their sense of security, their foothold.

As time went on, savings were exhausted and the family had to turn to the relief agency and to exist on its meager allowance. Self respect was dragged into the mud. Always accustomed to paying rent, they now found themselves in no position to do so. Gas, electricity, telephone, all those things that tend to make living comfortable, had to be done without. Kerosene lamps, small oil burners, or cheap coal stoves now became the sources of light and heat.

The children who were formerly well dressed now had to be thankful for the cast-off clothing of others. Is it any wonder that many of them rebelled and became disagreeable, disobedient, and ugly toward their parents, or developed symptoms of so-called nervousness as expressed in fears, super-sensitiveness, physical complaints without organic basis, or in anti-social activity such as stealing and truancy?

In the homes of the poor, always on the ragged edge, all this has not shown itself so startlingly as in the homes of the just above marginal to comfortable group. Among these were the citizens who had struggled to get ahead. Many had begun to buy their own homes—to be sure, covered with heavy mortgages. Soon they saw their homes lost. Others of this group had savings either in so-called savings banks, in building and loan associations, or in commercial banks. One after another these institutions closed their doors. Then came the bank holiday and some of our

mighty banking institutions are now being liquidated.

Is it any wonder that one finds child after child, especially among the adolescent group, completely disillusioned about home owning, saving money for that rainy day, or trust in the honesty of his fellow man, particularly those in high places?

And what is the effect on the child whose father is a suicide? Not all those who suicide are fathers of families, but a goodly number of the approximately 23,000 who in 1932 so ended their lives were. Many, too, are discouraged adolescents who have found life not worth living. And Frederick L. Hoffman,¹ statistician, states that the situation "imperatively demands drastic social interference if a much more substantial rise to higher figures is to be avoided."

In our own clinic as we compared the material of the last several years with similar material previous to the depression we were struck at once with the greater complexity of emotional involvement. Hardly any case referred in these depression years fails to show evidence of the effect of the depression. In many instances this is not so much in the nature of the production of the problems presented but rather in the attitudes of the parents toward them. A characteristic statement of parents is the following: "Oh, I know I should try to understand the boy, but with all my other worries . . ."—the outgrowth of the depression, such as loss of job, home, savings, or extreme readjustments in living conditions such as moving in with in-laws, or into poorer neighborhoods, etc.—"his behavior drives me frantic." Some parents are a bit more honest and admit that their own emotional troubles are the cause of the child's conflict. May I here cite in highly abstracted form a case history that illustrates dramatically the effect of the parental problems on the life of

the child and the child's reaction thereto. In passing, let me state that, except for detail of the specific set-up, this type of problem has been a relatively common one since the depression began.

Mr. and Mrs. R. have been married 10 years. They have one child, a girl of 8. Mrs. R.'s endocrine state is such that she has not conceived again. Mr. R. has until these years always earned a good salary. Mrs. R. has had about everything of material goods she wished for. She was extravagant always and she found it difficult to adjust herself to the changing status of her husband's income. The little girl was over-protected and somewhat spoiled by both parents, and particularly by the father to whom she was very close.

With the reduction in income it became essential that the husband and wife agree on expenditures. However, the wife continued her extravagance or rather now failed to manage the little there was to the satisfaction of her husband. Quarrels ensued, witnessed by the child, as usually is the case. She was torn between father and mother. The father began to stay out late, and the mother's suspicions in due course were verified—there was another woman who sympathized with him to whom the man had turned in his trouble. All of this was told the child.

The child became increasingly fearful. She feared her father would not be home when she returned from school. This fear became overmastering. She refused to go to school. She would wake up very early in the morning and begin to sob. Breakfast was eaten amid tears. Then she had to be taken to school, and as she got to the steps she would vomit what little breakfast she had eaten. She feared to enter the classroom unless the teacher was in the room. If the teacher left the room, the child was thrown into such an anxiety state that she could not remain in the

room but would have to follow the teacher. Only as some semblance of harmony were reestablished in this home did these symptoms let up.

Other children in somewhat similar situations may develop more severe physical symptoms than just vomiting, and are seen in dispensary or consultation rooms and treated for this, that, or the other physical condition, when in fact the physical complaints are but symptom formation brought about because of emotional conflict states.

Another common complaint in which the depression plays a prominent part is stealing. To be sure, children stole before the depression, yet basically stealing is a "get even" reaction, and therefore is one well suited through which the child can express his feelings of unfair treatment. Such stealing may be money from the home, or the holding out of change when sent to the corner grocery, or the more serious crime of holding-up or breaking into homes and stores.

Children who previously had their little allowances are apt now to pilfer small change in order to continue having ice cream cones or candy. In some instances unsatisfied hunger adds to the urge. In other instances material possessions have become overvaluated. The child had built his feeling of security upon such possessions and now, when that feeling of security and equality is badly shattered in all other respects, must enhance it through possessing things and under the circumstances that means stealing them.

Truancy in our experience is not so common an outgrowth of depression factors in young children as in older ones. In fact, we believe the truancy rate has declined to some extent among younger children of poor families because of the warmth of the school building and the food served there. Also the greater sympathetic understanding of school teachers has con-

tributed in our experience to a reduction of truancy. Among adolescents, however, certain truancy cases are the direct result of the depression. In the early years of the depression it was easier for the boy and girl of 16 to 18 years to get a job than for father or mother. Many a child seeing the sad financial plight chose to absent himself from school and seek to better the family fortune.

This brings us to a consideration of the effects on mental health of the child who not only truants from school but also absents himself from home. Many of the homeless boys, and girls too that one sees, left home because they either could not stand the constant nagging of relatives over their not having jobs when they themselves were perfectly aware none could be found, or they felt it best to get out so that there would be one less mouth to feed. Some few, very few, have had a fairly enjoyable time. They have seen the world and found it not so bad. The majority, however, seem to be having a miserable time of it. Most of them are disgruntled, weary, and footsore. Almost all of these are discouraged with life—they have found it bitter and without understanding. Dr. John Levy sums up well this problem of the homeless boy. He writes²:

One final question remains: What is going to happen to these fellows in the future? And this question is not nobody's business. As present economic conditions, as depressions repeat themselves, as these young men get older, reflect more and more frequently on the raw deal life seems to have given them, as they begin to read into the intangible causes of their downfall more specific motivation, as subsequent common working difficulties wipe out the heterogeneity of their background, as resistances are stirred up by authoritative opposition, stolid egocentricity will give way to more serious personality twists, more one-sided points of view, tensions, restlessness and need for motor outlets. From such social dynamics groups of psychopathic personalities are created. I wonder if revolutionists are not generated by the same

dynamics. I wonder if these same causes do not make revolutions possible.

And what about the homeless adolescent girls? To what extent are prostitutes truly recruited from their number? In Cleveland, and no doubt it is not an exception, each year of the depression has seen a greater number of girls picked up because of street soliciting. "The (police) department records also show that the girls arrested on vice charges today are much younger than they were in former years. The conclusion is that even youth has not been an influence in getting jobs in the past years."³

I have purposely avoided discussing the effect of malnutrition on the mental health of the child. With that phase all public health officials are fairly familiar although one could question to what extent the mental implications of malnutrition are understood. Cuts in school examination budgets, physical and psychological, will unquestionably lead to neglect in the correction of remediable defects and the proper placing of children in classes where they can achieve satisfaction. Out of such neglect divers kinds of problems arise—day-dreaming, inattentiveness, stubbornness when corrected for something the child is not able to control, bullying on the playground as a get-even reaction, truancy, etc. Attention, too, should be called to such economic measures as the elimination or sharp curtailment of shop courses of one kind or another, music, art, etc. Not only is this limiting the educational opportunities of all children but such elimination makes impossible the proper adjustment scholastically of many retarded children who find the three R's as taught beyond their ability to comprehend. Many a child will therefore be forced to serve time, all the while building up unhealthy emotional attitudes toward at least this phase of his life situation.

The best study of the effects of the depression on the mental health that has come to the attention of the writer is *An Unemployed Village*, by Paul Lazarsfeld.⁴ This study of the inhabitants of Marienthal, a village of Lower Austria, emphasizes "that parallel with the narrowing of the economic scope of these people, their psychic life has contracted." This psychic attitude the author defines as resignation, and he goes on to state, "this contraction of wants has a limit which cannot be exceeded. If it is reached, and if the external pressure continues to increase, the result is a catastrophic physical and psychic collapse." He finds that this holds true for children as well as adults.

In conclusion, permit me to state that, in my opinion, if ever there was a time for constructive work in the field of mental hygiene, now is that time. Only the unthinking can question the serious effects of these depression years on the mental health of both adults and children. In this field the morbidity rates have gravely increased.

Free Medical Care for the Unemployed in Czechoslovakia

PROVISION of free medical care for the unemployed is to be organized and supervised, according to a recent ministerial decree, by a national council of government officials and representatives of trade unions and medical societies. The actual medical work will be done by local committees throughout the country. The unemployed and their families will be given, in case of illness, medical and hospital care and

medicines and other articles necessary for the treatment of illness. The cost of the medical care will be borne by the Social Insurance Institute, the Ministry of Public Health and the druggists' organizations. The physicians will give their time free of charge.

This system of relief has no connection with social insurance.—*Deutsche Zeitschrift für Wohlfahrtspflege*, Berlin, Aug., 1933.

The Treatment of Trade Wastes*

L. F. WARRICK, F.A.P.H.A.

State Sanitary Engineer, State Board of Health, Madison, Wis.

INDUSTRIAL developments, such as have taken place on a gigantic scale during the past two decades, are largely the products of applied research. Intensive study with ingenious application of scientific facts or findings on a practical and economical basis have been responsible for much of our progress, particularly in the phenomenal development of mass production in this country. The trend has been steadily to increase production, efficiency in the utilization of raw materials having often been sacrificed in the efforts to speed up the wheels of industry. In recent years, however, there has been a tendency on the part of manufacturing concerns to give such matters more attention and apply research to reducing their industrial wastes for economic reasons as well as to solve problems confronting them involving the abatement of atmospheric and stream pollution.

The public has become increasingly aware of the harmful effects of unrestricted stream pollution. The uses of natural waters for drinking and domestic purposes; for watering of stock; for industrial water supply; for propagation of fish, oysters, and other aquatic life; for navigation; for power production; for agricultural development involving irrigation; and for recreational purposes, including bathing, boating, and fishing, particularly for

game fish—all these uses have been adversely affected in some degree by utilizing the same waters for the disposal of sewage and industrial wastes. Streams have been so grossly polluted in some cases as to render them absolutely unfit for normal uses. The result has been a growing demand that our natural waters be kept in a reasonably clean condition.

Public demand for clean streams in this country is evidenced by legislation enacted by many states and the federal government. The early laws tended to be absolutely prohibitory in nature, and were in a number of cases impractical of enforcement. Numerous damage suits arising from unrestricted pollution of streams, however, have been instituted, and the courts have in many instances upheld the rights of riparian owners under the common law to receive the waters flowing through their property "undiminished in quantity and unimpaired in quality."

Law enforcement alone does not provide the solution of many problems of pollution by industrial wastes. There are technical and economic, as well as legal, aspects to be considered. Accordingly the trend in recent years has been toward the establishment of governmental, industrial, and other agencies to undertake coöperative studies, to work out suitable means of reducing these wastes to a minimum, and to bring about the necessary stream improvement.

Industrial groups are becoming increasingly aware of the advantages of collective action in solving some of

* Read before a Joint Session of the Central States Sewage Works Association and the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

their common problems of waste utilization or disposal, as evidenced by the employment of engineers especially for this purpose by such organizations as the American Pulp and Paper Association and the American Petroleum Institute. There is already much evidence to show that the programs adopted by these various agencies are producing definite results and are materially beneficial in cleaning up the lakes and streams of the country.

The general policy underlying the various programs through which these results are being obtained calls for: (1) waste utilization to the greatest possible degree, and (2) if a pollution problem still exists, installation of any effective and practical method available or capable of being developed to treat and dispose of the waste in a satisfactory manner. With certain wastes, such as those produced in pulp and paper mills and in corn products plants, it has been found that by carrying waste utilization to its economic limits, pollution problems have been entirely eliminated or greatly minimized; and in these particular cases that the value of the substances recovered materially exceeds the cost of installation and operation of the recovery systems.

In order to illustrate the trend in procedures instituted to secure the solution of industrial waste pollution problems, the program being carried out by the Wisconsin State Board of Health may be cited. Activities relative to this program have for the most part been with the coöperation of the industries affected and in the main have included (a) the determination of the polluttional character of wastes from the state's larger industries, (b) research on and investigation of economically feasible ways and means of utilizing and of reducing the volume and strength of these wastes, and (c) educational and promotional measures to secure voluntarily indicated improvements. Steps taken

in dealing with three of the major industrial wastes problems, are briefly outlined:

Pulp and Paper Mill Wastes—Waste utilization and stream improvement activities by the Wisconsin pulp and paper industry and state agencies were started in February, 1926, following a meeting with mill executives held in Milwaukee. At this meeting it was pointed out that the mill wastes constitute one of the principal sources of stream pollution, but that no practical and economical methods of recovering or treating some of these wastes had yet been developed. Accordingly it was decided to seek coöperatively a solution of the various problems presented. To this end the industry appointed a committee of 7 to work with state officials in inaugurating and carrying out a definite program.

As a first step in this program all mills were called upon to determine fiber losses and take prompt action to reduce them to a minimum. With equipment available it was considered possible to render fibrous wastes negligible from the pollution point of view.

All pulp and paper mills in the state have been visited at intervals, to ascertain what steps had been taken in reducing objectionable fibrous and chemical wastes to a minimum and to foster further activity. Studies to obtain data for determining the fiber content and the polluttional value of wastes from each mill and for evaluating improvements in mill equipment and operation have been carried out in 1926, 1929, 1931, and 1932. Results of these studies have been published.^{1, 2, 3} In most of the mills efforts were being made to reduce white water wastes to a minimum through the installation of new "saveall" and recirculation systems. In some mills the fibrous wastes have been reduced to a practically negligible quantity.

This pulp and paper mill waste utilization and stream improvement program has been continuously carried on with the assistance of the committee on waste disposal of the Wisconsin pulp and paper industry. The effectiveness of chlorine-ammonia treatment for slime control in white water systems in pulp and paper mills has been further demonstrated during the past 2 years. Accordingly it is anticipated that more widespread use of information obtained will be effected during the coming year in establishing recirculation or closed systems for the white water, further reducing pollution by fibrous material.

It is further understood that progress has been made in the development of recovery processes for chemical wastes, such as produced in sulphate and sulphite pulp mills. Methods have been established for the re-use of lime sludge, which is produced in the operation of sulphate pulp mills, or its disposal as agricultural lime. Sulphite waste liquor utilization experiments are being conducted. One mill, which has been conducting pilot plant tests of the Howard Fractional Precipitation Process has reported: (1) that the process is commercially feasible to install and operate; (2) the values under Wisconsin conditions of the recovered products for making fresh cooking acid and for a boiler fuel will carry the process and show some net profit; (3) that the tail-liquor effluent from the process has much less oxygen demand than the untreated liquors and probably less toxicity to fish life. The next step will undoubtedly be a commercial scale demonstration of this process.

Studies were conducted to determine just how wastes from pulp and paper mills may interfere with the use of a stream for the propagation of fish. It is fairly well known that fish may be affected by pollution in any or all of the following ways: (1) direct killing through toxic constituents; (2) changes

in natural conditions, such as depletion of dissolved oxygen, so that fish seek another habitat either because of the condition of the water or the effect the wastes have on plants or lower animal life constituting their food; and (3) interference with the development of fish life and young fish, that is, influence on the reproduction of the species.

In comparing sulphite and sulphate pulp-mill waste liquors it was found that a direct toxic effect on the game fish used in the experiments might be expected when the wastes were diluted less than 1 part in 200 by volume. The wastes did not differ greatly with respect to the degree of dilution required to avoid destruction of fish by their poisonous constituents, presumably mercaptans or sulphur compounds. However, the sulphite wastes had a much greater avidity for oxygen than the sulphate wastes. Since these sulphite and sulphate wastes would probably deplete the dissolved oxygen in a stream below the critical amount necessary to sustain fish life before the limiting dilution of 1 part in 200 for toxic effects was actually reached, the most significant basis of comparison is their oxygen demand. Their relative effect on fish foods or reproduction of the species cannot be readily measured with our present knowledge.

If these wastes were compared according to their suspended solids or pulp fiber content, there would be practically no difference between them. Tests indicate that pulp fiber does not ordinarily accumulate in, and clog the gills of, fish causing death by suffocation. There is, however, the possibility of an indirect effect if fibers and other solids settle to the bed of a stream and decompose there, using up the dissolved oxygen necessary to support fish and other aquatic life.

Milk Plant Wastes—During the period 1927–1930 experimental work was conducted with 5 methods of treat-

FIGURE I—Trickling filter for the treatment of milk plant wastes

ment for both creamery and condensery wastes at DeForest, Wis. Preliminary results were published during 1929.⁴ Further studies and observations along with results obtained in Iowa, Ohio, Michigan, and elsewhere, having shown

the feasibility of efficient and economical treatment of milk plant wastes by direct discharge on crushed rock filters, 10 full scale treatment systems of this nature have been designed and installed in Wisconsin since 1930.

FIGURE II—Rotary distributor used in dosing a trickling filter for milk plant wastes—under winter operating conditions

FIGURE III—Bleeder at the center of the rotary distributor of a milk waste filter to prevent freezing difficulties during winter operation

Further progress has been made during the past year in developing ways and means for effective treatment and inoffensive disposal of milk plant wastes. Trickling filter installations made during the preceding 2 years, based primarily upon the previously reported experimental work at DeForest, utilized tip-troughs for periodic discharge of the wastes over the filter surfaces. Slime accumulations on the distribution boards resulted in uneven dosage of the larger filter units. Accordingly two large milk waste treatment plants installed during 1932 were equipped with rotating distributors for the filters and, in one case, an automatic timing device for regulating the filter dosing cycle. Operating efficiency studies have been made at all of the milk waste filter installations completed to date. Results obtained have indicated that these trickling filter systems accomplish very effective removal or modification of pollutorial substances in the milk wastes.

Cannery Wastes—In October, 1925, cannery wastes were discussed before

the Convention of the Wisconsin Canners' Association at Milwaukee, and difficulties encountered in disposing of pea cannery wastes were outlined. It was pointed out that no satisfactory method of treating such waste had yet been developed, and that, while this was the problem of the industry, the state would cooperate in reducing objectionable stream pollution. A definite appropriation of \$500 by the industry was made to start experimental work during the following summer, in order to develop, if possible, practical and economical means of treating these wastes. The appropriation was made, and the results of this investigation are included in Part III of the report, *Stream Pollution in Wisconsin*. This work indicated that approximately 75 per cent of the pollutorial value of the wastes could be removed by chemical treatment, on the basis of 5 day B.O.D. results.

On the basis of information obtained during 1926, chemical treatment plants have been installed and operated at Wisconsin canneries where pollution

FIGURE IV—Rotary screen unit for removal of large solids from cannery wastes. Wastes are collected in the screen sump and pumped to the chemical treatment plant or to areas utilized for disposal by soil absorption

problems existed. Thirty-three treatment plants of the chemical precipitation type were available for treatment of cannery wastes in Wisconsin during 1933. In addition, most of the canneries have provided preliminary treatment for their factory wastes by screening, and some are using ground absorption for final disposal where soil conditions are favorable. Studies conducted of the treatment of wastes produced in the canning of beets indicated that by the application of 14 lb. of lime and $4\frac{1}{2}$ lb. of ferrous sulphate per 1,000 gal. of the composited washer, peeler, blancher, capper and other wastes incident to the beet canning process, a reduction of 96 per cent in suspended solids, and 50 per cent in 5 day B.O.D. can be effected in a fill and draw type chemical precipitation plant. In the treatment of carrot canning wastes the use of $7\frac{1}{4}$ lb. of lime and $3\frac{1}{4}$ lb. of ferrous sulphate per 1,000 gal. of wastes effected a reduction of 98 per cent in suspended solids, and

67 per cent in 5 day B.O.D. using the fill and draw process with a 2 hours settling period for the treated wastes.

In view of limited dilution available at the cannery where these studies were conducted the wastes were pumped into the dosing tank of a trickling filter at the municipal sewage treatment works. The effluent from the plant showed 82 p.p.m. total solids, 57 p.p.m. suspended solids, and 88 p.p.m. 5 day B.O.D. during the period these cannery and other wastes were being applied, entirely satisfactory for final disposal in the small stream available for dilution of the wastes.

A cannery company packing kraut located near the headwaters of a small stream flowing through a dairy region was confronted with a problem of so disposing or treating their wastes as to prevent a nuisance and "kraut" tastes in milk furnished by the cattle using the stream as a source of water supply. Lagooning or disposal of the wastes by soil absorption was impractical because

of the character of the soil and other local conditions. Studies were conducted and a treatment system was installed, including removal of gross solids by a 40 mesh rotary screen, chemical precipitation using alum and lime in fill and draw tanks, sand filtration using filters equipped for backwashing, and chlorination for the filter effluent. The treatment process has been successful in overcoming the objectionable conditions previously experienced.

Much of the activity outlined and improvements effected have been the result of coöperative effort. Research conducted by industry, state, and other agencies has pointed the way toward the solution of these waste utilization and stream improvement problems. When the effectiveness of a waste treatment or recovery process has been definitely demonstrated, and particularly when it can be shown that some financial return will be realized in con-

nection with such process, much objection on the part of industry to expenditures for improvements is overcome. A wide diversity of trade waste problems exists in this country, but it is believed that the common approach to their proper solution lies in mutual understanding and coöperation.

In conclusion, it is urged that the coöperative policies and procedures be extended and further developed by government, industry, and others concerned to the end that the most effective and economical solutions for industrial waste problems may be most speedily and satisfactorily accomplished.

Why Not Save Hospital Beds?*

MARGUERITE A. WALES, R.N., F.A.P.H.A.

General Director, Henry Street Visiting Nurse Service, New York, N. Y.

FOR years Dr. Dublin of the Metropolitan Life Insurance Company has been urging visiting nurse organizations to place greater emphasis on the care of communicable disease in the home, even if it became necessary to reduce the maternity programs, which he considered unduly large. While we still believe the emphasis on maternity care is justifiable because of the opportunity for health teaching, recently our attention has become more definitely focused on communicable disease control by some studies made in New York City.

In 1931 a survey of the communicable disease hospital needs in one of the large boroughs of New York City was made under the guidance of a committee appointed by the State Charities Aid and working in coöperation with the Department of Hospitals and the Department of Health. Up to that time apparently no one had considered the relationship between a visiting nurse service caseload and the communicable disease hospital needs of a given community. In fact, some of the members of the committee saw no reason why the visiting nurse records should be included in this study. However, the director of the study, Anna Phillips, herself a public health nurse, insisted, and the significance of the visiting nurse figures is apparent in her report. As one member of the committee expressed it, "When I saw those figures showing

that the Visiting Nurse Service had given care to more patients in the home than were sent to hospitals I went straight to the Commissioner." To his surprise the Commissioner replied, that, of course, the Visiting Nurse Service had cared for communicable disease patients in their homes for many years.

This survey raised a number of questions in regard to the Visiting Nurse Service. First, was it true that the Visiting Nurse caseload was limited to milder cases? Second, was it true that a great many secondary cases developed when patients were kept at home? Third, did the Visiting Nurse Service send its sickest patients to a hospital and then omit the hospital deaths in its final fatality rate?

To answer these questions we made an analysis of our own records for 1932. As it was not possible to make a control study of hospital cases at this time, it was decided to use the same area (the borough of the Bronx) and the same 4 communicable diseases (diphtheria, scarlet fever, whooping cough, measles) as in the Phillips survey of 1931. This study showed that 12.4 per cent of the patients had complications before admission to the hospital; 16.6 per cent developed complications after admission—a total of 29 per cent of hospital cases with complications.

The study of visiting nurse records for one district (315 cases) showed 26 per cent of the cases had one complication, and that a total of 35 per cent had one or more complications. It is not possible to make a comparison between the hospital and Visiting Nurse

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

Service figures, since the present records of the Visiting Nurse Service do not indicate whether a complication arises before or after admission to the service; and it was also learned after the study was made, that the hospital total did not include some of the minor complications which were used in the visiting nurse study which was based on the classification of Willard Parker Hospital. Furthermore, as Miss Phillips points out in her report, no conclusions can be drawn from such a statistical study as there is no way of determining the previous condition of the patient, his susceptibility to disease, and so forth. The study did indicate, however, that the Visiting Nurse Service caseload is not limited entirely to the milder cases.

In the study of secondary cases it was decided to omit whooping cough and measles, as these are so often diagnosed too late to prevent secondary infection, and also diphtheria, as the number of cases was too small to be of interest.

It is significant that in the 309 families where scarlet fever occurred there were 124 families with younger children where no secondary cases developed. In the 38 families where there were 2 or more cases of scarlet fever there were only 19 patients where the onset of disease developed after the 7th day from the first visit of the nurse; a total of 5.4 per cent of the entire number of patients with a secondary case which developed after the 7th day.

With this low rate of secondary cases is it not reasonable to assume that risk of secondary cases (considering the low fatality rate) is less than the risk of cross-infection in overcrowded hospital wards?

Dr. Charles Hendee Smith, for many years director of the Children's Service in Bellevue Hospital, New York City, recently stated in a radio address that the best place for a sick child is in the

home, with 4 exceptions: for major operations; where special treatment such as transfusions are needed; where special equipment is needed for difficult diagnosis; or where home conditions are impossible. In the care of communicable disease, it seems to me that the question of home conditions is of primary importance. Dr. Best, Chief of the Bureau of Communicable Disease, recently requested that when our nurses ask for a diagnostician in undiagnosed cases where the family is unable to pay for a private physician, the nurse also indicate whether hospitalization seems advisable, thus showing the importance of the nurses' judgment on the home situation.

Of the 19 families where secondary cases developed after the 7th day, only 1 case was considered by the nurse as entirely satisfactory for home care.

During 1932 all cases of scarlet fever, measles, whooping cough, and diphtheria that were sent to hospitals after being seen by the Visiting Nurse Service, were followed up, and the deaths which occurred in hospitals were included in the total deaths for the year. In the 2,648 cases seen by the visiting nurses in the three boroughs of New York City served by the Henry Street Visiting Nurse Service, the deaths amounted to 16. Of these, 9 died in the hospital; 7 of these cases should be considered as "not nursed" cases since the nurse either made only 1 or 2 visits to urge hospitalization, or no nursing care was given as the physician in charge did not think it necessary. Nevertheless, the 16 deaths are included in our case fatality rate for the year. In 8 cases it was the nurse who first suggested and urged medical care or calling an ambulance.

In the 956 cases of scarlet fever death occurred in 2.

We appreciate the fact that further study is needed since up to the present Henry Street is the only nursing or-

TABLE I
SCARLET FEVER, 1932

	<i>Total Reported Cases</i>	<i>Total Deaths</i>	<i>Case Fatality Per Cent</i>	<i>Death Rate per 100,000</i>	<i>Per Cent Hospitalized</i>	<i>Per Cent Served by V.N.S.</i>
<i>Four Cities Over 1,000,000</i>						
New York City	21,093	134	.63	1.86	25.8	
3 Boroughs Served by V.N.S.	11,726	76	.64	1.73	28.5	8.1
Philadelphia	6,549	48	.70	2.46	67.0	3.0
Detroit	6,549	41	.60	2.74	47.0	7.5
Chicago	7,637	137	1.80	3.90	41.0	—

ganization which has followed up its hospital cases and included these in its final death rate. However, with the figures available from other cities we believe we have some facts which should set us thinking.

When preparations for this paper were begun it was taken for granted that the question of the safety of the care of communicable disease in the home in a generalized visiting nurse program had been settled at the Annual Meeting of the Association in 1925. At that time a forum was held on the question "Is the Public Health Nurse a Carrier of Infection?" Previous to the meeting, questionnaires had been sent to visiting nurse directors and health officers from coast to coast. From the replies received it was apparent that there was no *recorded* instance of a nurse carrying disease from patient to patient, and that many health officers were convinced that it was safe to carry on such a program. Furthermore, from the discussion which followed at the meeting many of us went away with the feeling that the safety of including this

service in a generalized program was an established fact. However, in 1933, it was found that in the 10 largest cities in the country there were only 5 visiting nurse organizations which were knowingly giving care to communicable disease patients.

In the tables the study has again been confined to scarlet fever. As Miss Phillips pointed out, scarlet fever is considered a major cause of seasonal overcrowding in hospitals. Her report showed that the average stay of a scarlet fever case in a New York hospital was 26 days. The hospital cost which she quotes for one hospital was \$8.86 per day in 1930, or an average of \$234 per case. The care of scarlet fever cases is then an important factor in city budgets.

Table I shows the 4 cities of over one million population. Here it is interesting to note that 3 cities have practically the same case fatality rate, and in all of these the Visiting Nurse Organization is permitted to give care to communicable disease patients.

One wonders, if a city can maintain

TABLE II
SCARLET FEVER, CHICAGO—FIVE YEARS

<i>Year</i>	<i>Cases</i>	<i>Deaths</i>	<i>Case Fatality Per Cent</i>	<i>Death Rates</i>	<i>Per Cent Hospitalized</i>
1928	4,335	78	1.8	2.40	34.4
1929	7,945	168	2.1	5.07	34.2
1930	9,599	199	2.1	5.89	32.1
1931	8,209	177	2.2	5.13	35.4
1932	7,637	137	1.8	3.90	41.2

a case fatality rate by hospitalizing 25 per cent of its cases, as low as that of a city hospitalizing 67 per cent, why there should be an increasing emphasis on hospitalization? The families do not want to send their children to hospitals—the children do not want to go, and certainly the tax payers are full of protests against unnecessary costs.

Since New York and Chicago represent opposite points of view in regard to home care, we have made a study of hospitalization and death rate for the past 5 years, which is interesting. Chicago does not allow the nursing service to give care to communicable disease patients, and maintains a high rate of hospitalization. Its case fatality per cent and its death rate, however, do not indicate for a 5-year period that great gain has been made by hospitalization.

tions—but Chicago was able to achieve the most favorable infant death rate of any large city for 1932.

Table IV gives a picture of the increasing caseload of the Visiting Nurse Service for the past 5 years, the actual number of cases having trebled, and the percentage of total reported cases showing a great increase. Since we had not definitely made a follow-up study of hospital cases previous to 1932, it seemed advisable to give the percentage of hospitalization of cases seen by the visiting nurses. It will be noted that during the last 2 years 10 per cent of these cases were sent to hospitals, but neither of the 2 deaths in 1932 occurred in the hospital, and the records indicate that in 1 case the nurse made every effort to have the patient hospitalized but was overruled by the family and physician.

TABLE III

SCARLET FEVER, NEW YORK CITY—FIVE YEARS

<i>Year</i>	<i>Cases (Five Boroughs)</i>	<i>Deaths</i>	<i>Case Fatality Per Cent</i>	<i>Death Rate per 100,000</i>	<i>Per Cent Hospitalized</i>
1928	10,586	69	.65	1.08	15.9
1929	7,952	68	.85	.99	18.8
1930	7,592	57	.75	.82	20.0
1931	11,900	84	.70	1.18	21.9
1932	21,093	134	.63	1.86	25.8
<i>Five Year Average</i>					
	New York City		.69	1.18	21.5
	Chicago		2.01	4.46	35.3

In New York City it will be noted that the death rate and case fatality per cent remain approximately the same throughout the 5-year period, and its per cent of hospitalization is much lower than Chicago. Here the Visiting Nurse Service is permitted to give care to communicable disease patients in the home.

A close-up picture of the average for the 5-year period is given in this chart for Chicago and New York City. The question naturally arises as to whether Chicago's emphasis on hospitalization is because of unusually bad home condi-

It seems particularly interesting that there are no deaths in the cases referred to hospitals by the visiting nurses. A study should be made of the relative time which elapses between the date of onset and date of admission to hospital on cases seen by the Visiting Nurse Service and those who have no such nursing supervision. The main object of this paper is to stimulate further study on this phase of public health work.

The public needs more facts on this question of home care. At Henry

Street we have developed communicable disease technics which have been approved by our Medical Advisory Committee and accepted by the Health Department, and no protests have come from the community served. This is interesting in view of the comment of the director of a visiting nurse organization which is not permitted to include the care of communicable disease in its generalized program. She writes: "Of course you and I know it is perfectly safe, but until the public knows it and believes it, it will not be done with the approval of the public."

In conclusion, there is one further point which I wish to emphasize. It is obvious that when a patient is sent to the hospital very little education in the principles of communicable disease control can be done in the family. In his article "Facts, Fallacies and Assumptions Concerning Communicable Dis-

ease Control,"¹ Dr. Carl E. Buck maintains that "the prevention and control of communicable disease is primarily the responsibility of the individual and the individual family. The educational efforts of the public health nurse constitute the most important factor in the development of this sense of responsibility in the individual."

Can there be any further doubt, then, in these days of measuring budgets and values of service, that this safe and economical way of providing care in the homes of communicable disease patients is of the utmost importance in a visiting nurse program? And finally, is it too much to hope that health officers will soon universally agree that the visiting nurse is a valuable aid in the control of communicable disease?

DISCUSSION *

LOUISE KUCK TOOKER, R.N.

Superintendent of Nurses, Health Department, Cincinnati, Ohio

A TRUE public health nurse, with eyes open to every opportunity of service, carries on a constant battle against communicable disease whether that function is listed among her agency's activities or not. Working in

homes, clinics, and schools, she does not wait until the community is faced with a communicable disease epidemic before she starts to teach age old habits of cleanliness and decency wherever she can.

Very definitely the public health

* Abstract.

nurse can insist upon keeping children away from sick people as the tuberculosis nurse has learned to do on her first visit to a family. This isolation is no less important in some other illnesses. It is equally important to keep the sick child away from other children, especially if he is classified as "not very sick" or "just getting a little cold." For, after all, does not the patient do most damage in the way of infecting others before he is sick enough to go to bed?

The public health nurse working in the school has a fine chance to enlist the coöperation of parents and principals in keeping children with colds at

home for a few days. In one of the Cincinnati suburban schools a committee from the P.T.A. assists in notifying parents that children are being sent home, and, if necessary, conducts little ones home. They have arranged cross files of friends with whom a child may stay if the mother is away.

Who better than the public health nurse can bring about early diagnosis and reporting of cases? Even some of the wisest mothers say to the nurse "I just thought I'd ask you; I hate to call in the doctor for every little thing." Yet seldom does a mother delay calling the doctor after the nurse points out the importance of doing so.

PASADENA

A.P.H.A. Convention City for 1934

AS Pasadena has been honored by the A.P.H.A. in being selected as a meeting place for their convention in 1934, the city extends a most cordial message at this time to all who are planning to visit with us. It is that you will come as honored guests and for the length of your stay find happiness with us and carry away when you depart a bit of that glow about your hearts that your coming has given to us.

When Don Caspar de Portola and his band of explorers passed north in 1770, through the region now known as Southern California, they camped for a night near an Indian village in the foothills, overlooking a fertile valley. In the morning they awoke to view a spectacle of mountains and flowering valleys that brought forth exclamations of amazement and delight.

One hundred and four years later a group of sturdy pioneers from Indiana searching for a place to replant American homes and ideals that would bring happiness and security to their children selected that same spot which had delighted Portola and his followers. In 1875 this settlement, known as the Indiana Colony, formally adopted the name "Pasadena." It is a word derived from the Chippewa Indian dialect, meaning "Crown of the Valley." Since these early days many thousands from all parts of the globe have found here an ideal spot in which to live or spend a vacation.

The climate permits flowers to bloom and grass to be green the year around. Summer or winter, the days are delightful and the nights are cool. Weather Bureau statistics for 50 years show that January has an average temperature of 55, July of 71, a variation of 16 de-

grees. The average year has twelve days when the thermometer registers above 90, and thirteen days when it goes below 40.

City Hall

Within the city are many beautiful buildings and homes divided by streets lined with trees unsurpassed in nature's grandest contribution to her loveliness.

On the north are lofty mountains whose beauteous spots are easily accessible by well paved roads open summer and winter for those who love the mystifying grandeur of mountain surroundings.

To the west is a great natural gorge, the Arroyo Seco, its bed beautified with parks and its sides dotted with tile roofed villas.

To the south and east is California's great citrus domain.

Eleven miles away is the downtown

The Rose Bowl

center of the largest city in western America, the motion picture capital of the world.

There are a score or more of seaside resorts within 2 hours of Pasadena by interurban or motor car. Within 4 hours' drive to the south lies Mexico, and within nearly the same time north the giant redwood trees, the many lakes, and other grandeurs of the High Sierras.

California Institute of Technology is in the front rank of American institutions devoted to technical education and research. Here are gathered professors of international repute in buildings and laboratories equipped with the latest instruments for scientific research. Approximately 500 students are enrolled from all parts of the world. Here is an institution worthy of one's visit, regardless of whether or not he is scientifically inclined. The famous Guggenheim Aeeronautical Experimental Station is located at the Institute.

Huntington Library—Ranking among the world's greatest museums, the Huntington Library comprises about 200,000 rare books and upward of 1,250,000 original manuscripts. The Huntington Art Gallery con-

tains the greatest collection of English portraits ever gathered under one roof. The collection is made up of 45 paintings—41 portraits and 4 landscapes—all outstanding works from the brushes of masters. The most famous painting in the gallery is Gainsborough's "Blue Boy," bought from the Duke of Westminster in 1921.

Mt. Wilson—On the summit of mile-high Mt. Wilson is situated the Mt. Wilson Observatory of the Carnegie Institution of Washington, D. C.—regarded as the world's foremost center of astronomical research. Equipment includes the world's largest telescope. The museum with its exhibit of astronomical photographs is open to the public for an hour each afternoon. Aside from the observatory, the summit affords an inspiring view of the San Gabriel Valley and the coast line beyond, and a delightful inn and dining room are on the summit. A very interesting astronomical lecture is given every Friday night.

Busch Gardens—A short distance south of the bridge are the famous Busch Gardens. The gardens are situated on the estate of the late Adolphus Busch, but are open to the public.

Colorado Street Bridge

Comprising 30 acres of beautiful landscaping, novel garden effects and rare horticultural specimens, they constitute one of Southern California's most renowned scenic attractions. The gardens are built on the east slope of the arroyo, and the natural topography of the land has permitted landscaping achievements hardly possible anywhere else. In variety of floriculture and magnificence of landscaping, they are said to excel all others. Along the eastern bank of the arroyo, winding paths, now climbing, now descending, lure one through a veritable fairyland of flowers and shrubs and trees, thickly set with secluded resting spots and populated by song birds. On the western side of the ravine, the steep, high cliffs are bright with the myriad colors of wild flowers. Scattered through the gardens are groups of statuary depicting familiar scenes from fairy tales. Tucked among the flowers and shrubs are tiny statues of gnomes and brownies.

Fourteen miles of walks wind through the gardens, twisting, turning, offering a new and beautiful picture at every bend.

The Los Angeles County Health Department, under the administration of Dr. J. L. Pomeroy, has developed an outstanding example of the district health center idea, and the County in coöperation with the various districts, has erected beautiful buildings well designed for this type of public health administration. These centers are well worth visiting, and it is planned to hold the first Health Officers Section meeting in one of them.

All the world knows Pasadena—its fame as a city of homes—the place where the quest for an ideal has ended. The inviting hospitality of Pasadena, its famed hotels, its unique recreational features, the delightful resorts of the Pacific, the broad expanse and mystery of the desert beckons you. We want you to share our pleasures and enrich us with your presence.

STATE CONTROL OF MILK PRICES

THIRTY years ago the Supreme Court of the United States held that reasonable regulation of milk in the interests of the public health was a valid exercise of the police power of a state. Since that time this court has handed down a number of decisions sustaining the power of the states to regulate the sanitary production of milk, and upholding the right of the states to prohibit or prevent the entry of impure milk and diseased cattle, and to delegate the supervision of milk supplies to local health authorities.¹

On March 5, 1934, the Supreme Court went even further when in a divided opinion it upheld the right of a state to determine the retail price of milk when an emergency exists. This noteworthy five to four decision sustained as constitutional a New York law which was adopted in April, 1933, as the result of an exhaustive legislative investigation of the dairy industry. This law authorized the creation of a State Milk Control Board, empowered it to fix wholesale prices to be charged or paid for milk, and required it to fix retail prices. The law, to be in effect only until March 31, 1934, unless extended, was upheld by the New York Court of Appeals and now has the sanction of the highest court of the land.

In this notable decision, Mr. Justice Roberts points out on behalf of the majority of the court that milk is an essential article of diet, that it must be properly safeguarded, that the dairy industry is of vast significance to the economic life of the people, that there is a huge surplus of milk, and that a satisfactory stabilization of prices for fluid milk requires that the burden of surplus milk be shared equally by all producers and distributors in the milk-shed. The opinion also states that milk is not a public utility, but that the milk industry is one that is subject to proper regulation in the public interest.

"Price control, like any other form of regulation," says the court in conclusion, "is unconstitutional only if arbitrary, discriminatory, or demonstrably

irrelevant to the policy the Legislature is free to adopt, and hence an unnecessary and unwarranted interference with individual liberty." In the opinion of the minority of the court, the price fixing of milk is not regulation, but improper management of and dictation to private business.

The effect of this decision will, however, be salutary, not only with respect to milk regulation, but to the whole recovery program. In previous editorials in this *Journal*² the problems of the dairy industry have been discussed, and it has been emphasized that an increased consumption of pure milk is essential to national health. It is the function of the health officer to enforce and maintain high standards of sanitary milk production and distribution and then to attempt to induce the public to use this high quality milk in beneficial quantities.

The economic and sanitary aspects of milk are so interrelated that they cannot be separated. Up to the time of the depression, milk consumption was increasing because of public confidence in the safety of market milk. Reasonable sanitary regulations, adequately enforced, tend to protect the reputable dealer as well as the public. Price fixing, if fair to all, accomplishes the same end, since it permits legitimate and honest business to sell milk at a small and reasonable profit and hold its trade without unfair competition from unscrupulous racketeers who are more interested in profits on low-priced milk than they are in pure and safe milk.

Both prices and sanitary regulations must of necessity be adapted to prevailing local conditions. Standards applicable to a metropolitan area in the North are obviously different from those governing a rural district in the South. But one thing is certain, and that is that any community can have clean and safe milk at a reasonable cost. One element in the attainment of that goal is the universal pasteurization of all milk, except certified.

Health officials should dedicate their efforts to this ideal, endeavoring at all times to maintain quality milk supplies, preferably pasteurized, and sufficiently attractive in purity and price so that the public will increase its consumption of our most nearly perfect and indispensable food.

REVISION OF THE FOOD AND DRUGS ACT

WE have already published one editorial¹ on the bill now before Congress providing for a revision of the Food and Drugs Act. We believe that as far as the protection of the public goes in this regard, this bill is second only in importance to the fight put up by the late Dr. Harvey W. Wiley. The editorial in question followed closely the resolutions adopted at our meeting in Indianapolis, which we reprint here, as they have been published only in the *Year Book*, and we desire to call them to the attention of all of our readers:

RESOLVED, that the American Public Health Association:

1. Express its confidence in the purposes and principles of the Federal Food and Drugs Act now before Congress for action; and
2. Solicit the support of all members of the Association to secure the enactment into law of the objectives of this revision, and
3. That this expression of the views of the Association be made a part of the record of this meeting.

Since that time the bill in question has been before committees; hearings have been held; and a very strong lobby for its defeat, or a modification of it which to all intents and purposes will defeat its chief objects, have been organized. Indeed, some modifications have been accepted by Senator Copeland who is responsible for it in the Senate, and a new one has been drafted by persons employed by the drug interests.

These bills are being carefully watched by food experts who are connected with our Association, and the *Journal* will report from time to time on the progress of events. It does not seem wise at the present time to take any particular stand further than has already been taken, but to watch developments. Our object now is to call our readers' attention to the resolutions already published by our Association and to urge them to keep in touch with what is going on in Washington concerning this bill. We cannot emphasize too strongly our belief that the matter is deserving of the most careful study on the part of all interested in public health and of the closest attention to the progress of events.

ORAL HYGIENE

ALMOST before the ink on our editorial (March, 1934), on oral hygiene was dry, there came to hand two publications^{1, 2} which deserve wide reading. While we recognize and deplore the orgy of tooth pulling which the medical profession indulged in for several years for every ailment from pip to ingrowing toenails, but which has fortunately abated, we still feel that dentistry is too little considered by the general practitioner, who is apt to view it from cosmetic and nutritional angles, but not enough from the standpoint of general health.

For those doctors who still feel that dentistry is apart from medicine, we may point out that as early as 1561, it seems that the work of the great French surgeon Paré was influential in placing dentistry on a physiological basis, while, in 1771, the great English surgeon, John Hunter, published a book, *Natural History of the Human Teeth*, and 7 years later a second one, *A Practical Treatise on Diseases of the Teeth*.

To this day, Hunter's work is recognized as the first attempt at a classification of the teeth, and still stands practically as he made it. His studies on the anatomy of the tooth have seldom been equalled, and never surpassed, and today are the foundation stones upon which all such work stands. While Hunter apparently did not relate diseases of the teeth with systemic disturbances, he did appreciate the necessity of proper occlusion, pointing out that irregularities in the second dentition were more apt to occur in the upper jaw than the lower one, owing to the comparatively larger size of the permanent upper set of teeth than the lower. He went further and claimed that the teeth were more easily moved backward than forward, and were more apt to remain fixed when moved back than when moved in the opposite direction. Certainly when men like Hunter and Paré found it to their advantage to spend time on dentistry, it behooves us, with our present and greater knowledge, to do something of the same sort.

It seems that the first person to call serious attention to the danger of systemic involvement from infected teeth was Dr. Willoughby D. Miller, a collegiate graduate of the University of Michigan, and a dental graduate of the

University of Pennsylvania in 1879. After graduation he went to Berlin where he had the opportunity of working in bacteriology under Koch, and in 1889, wrote *Microorganisms of the Human Mouth*. In 1891 a second publication appeared, *The Human Mouth as a Focus of Infection*, and during the same year, a third, *Pathogenic Mouth Bacteria*, which contained 23 illustrations.

While this work attracted the attention of bacteriologists, there is not a great deal of evidence that it had much effect generally, though we must give particular credit to a number of dentists who recognized that something new, and of importance, had been introduced into the practice of dentistry. The great awakening of the medical profession to the danger of oral sepsis was due to Sir William Hunter who, as early as 1900, published his book, *Oral Sepsis*, which fell on deaf ears, but who in Montreal, October, 1910, gave an address on "The Rôle of Sepsis and of Antisepsis in Medicine," which had a marked effect.

Perhaps the great majority of American physicians will credit this medical awakening to the late Dr. Frank Billings, who wrote on the effect of localized infections in endocarditis in an article called "Mouth Infection as a Source of Systemic Disease,"³ and also published his book, *Focal Infection*.

The first dental college was organized in Baltimore in 1840 by Drs. Horace H. Hayden and Chapin A. Harris. These men tried to inaugurate the teaching of dentistry in relation to medicine at the University of Maryland, but the authorities lost the opportunity of founding the first university school of dentistry by rejecting the offer, and the institution founded by them was devoted specifically to the education of dentists. However, Dr. Harris is credited as being the pioneer through whose efforts dentistry became a recognized specialty of the healing art. In reading the biographies of prominent dentists, one finds a surprisingly large number who obtained their training at this school. In addition to his service in helping to found the first school for dentists, Dr. Hayden called the convention to order when the American Society of Dental Surgeons was formed in August, 1840, while Dr. Harris was the first editor of the first dental journal, 1839. Other facts show that Dr. Harris was interested in the teaching of dentistry before the foundation of the Baltimore College.

Harvard University, in 1868, was the first university to found a dental school in connection with a university, where the degree D.M.D. is still given, which some of the dental profession interpret as indicating some degree of condescension toward the dental profession as such. The first dean of the Harvard School was Dr. Nathan C. Keep, who served an apprenticeship in dentistry, then obtained the degree of Doctor of Medicine at Harvard in 1827. Dr. Keep will be remembered by many in connection with the Webster-Parkman murder case, as it was he who identified the remains of the victim by the dental work in Dr. Parkman's mouth, which he had done. The University of Michigan followed Harvard in establishing a dental school in 1875, and next, the University of Pennsylvania established its School of Dentistry in 1878. Many other dental schools in connection with universities now exist, the private dental school, like the private medical school, having largely gone out of existence, aided by the survey of the Carnegie Foundation begun in 1922.

The year before the founding of the Baltimore College of Dental Surgery, the *American Journal of Dental Science* was founded, and in 1840, the American Society of Dental Surgeons came into being.

It is to be regretted that more about dentistry as a profession cannot be included here. Perhaps the next step forward was the study of oral surgery,

which had a profound influence on the profession of dentistry. Oral surgery in some ways touches more closely the medical profession, including surgeons, than does dentistry. It is stated that until comparatively recently there were only two textbooks on oral surgery available, one which Dr. James E. Garretson published first in 1869, and the other by Dr. John S. Marshall. In 1900, Dr. Thomas L. Gilmer published the lectures given to the senior class of the Northwestern Dental School, but on account of the scarcity of literature up to a few years ago, oral surgery was taught largely as a didactic subject.

The men who may be credited with having done much to put the subject on a firm basis are Dr. Matthew W. Cryer, who became Professor of Oral Surgery at the University of Pennsylvania in 1896, Dr. Truman W. Brophy, of the Chicago College of Dental Surgery, Dr. Thomas L. Gilmer, of Northwestern University, and Dr. Cyrenus G. Darling, of the University of Michigan. Both Drs. Brophy and Cryer were students of Garretson, and at one time Dr. Cryer was his first assistant. The subject of dental surgery is now well established. During the World War dentists and oral surgeons had unusual experiences and did a tremendous amount in the scientific treatment of fractures of the jaws and in restoring the facial contour to desperately wounded soldiers.

Space does not permit of the mention of all who deserve credit in this line of work. The great object of this editorial is to interest practitioners in what is unquestionably a most important specialty of the healing art, and to encourage the reading of history which will show how much we owe to a profession which is too widely separated from the average physician of the present day. May both professions recognize their opportunities and come closer together for the benefit of mankind.

ASSOCIATION NEWS

RURAL HEALTH CONSERVATION CONTEST LAUNCHED

W. K. Kellogg Foundation Makes Possible New Rural Health Conservation Contest

FOR the first time whole-time county and district health units throughout the United States will have an opportunity, this year, of participating in a national health contest such as the cities of the country have been competing in for the past five years.

This contest is made possible through a generous grant from the W. K.

Kellogg Foundation of Battle Creek, Michigan. As many of our readers know, it is this same W. K. Kellogg Foundation which is carrying on such interesting and promising studies and experiments in rural public health work in its several units in Michigan.

The Inter-Chamber Rural Health Conservation Contest, like the City

Contest, is carried on by the Chamber of Commerce of the United States in coöperation with the American Public Health Association. The purpose of this new contest is to promote sound rural public health practices, particularly through interesting the business man in public health and fostering a more effective coöperation, coördination and integration of the work of the several organizations and groups interested in, or carrying on, public health programs. This competition will be conducted along lines similar to the City Contest except that only full-time county health departments or district health units will be eligible to partici-

pate. The only requirements for enrollment are that the county or district health units have a full-time health officer and that such county or unit be entered by a chamber of commerce located in the county or district and affiliated with the Chamber of Commerce of the United States. Already some fifty counties have signified their intention of enrolling.

Further data on the contest are available either from the Insurance Department, Chamber of Commerce of the United States, Washington, D. C., or the Committee on Administrative Practice, American Public Health Association, 50 West 50th Street, New York City.

SCIENTIFIC OR EDUCATIONAL EXHIBITS

FOR a number of years the American Public Health Association has had in connection with its Annual Meeting a non-commercial exhibit variously referred to as the Scientific or Educational Exhibit. Last year a special committee of the Association was appointed to take charge of this exhibit and develop it for the greater interest of the delegates. In the exhibit presented at the Indianapolis Convention a beginning was made in this direction.

It is the ambition of the Committee on Scientific Exhibits to develop a feature for our Annual Meetings which in its way may be as valuable a contribution to the Annual Meeting as are the papers on the programs of the scientific sessions. We believe that there are many important activities in the public health field which can be presented better through the use of the exhibit method than by the presentation of a paper.

The committee requests that any member of the Association who has

some new, interesting, or important matter to present, which lends itself to presentation by the exhibit method, get in touch with the committee through the Association office.

The committee, of course, reserves the same right as the Program Committee, to accept material offered within the limits of the space available. The committee is naturally desirous that material prepared for the Scientific Exhibit be interesting as to method of presentation as well as to content, yet we appreciate that expert technic and unlimited facilities for the preparation of an exhibit are not available to all public health workers. Members of the committee are therefore ready to offer suggestions and advice to prospective exhibitors.

Communications for the committee should be addressed to Homer N. Calver, Chairman of the Committee on Scientific Exhibits, American Public Health Association, 50 West 50th St., New York.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

George R. Allen, M.D., Champlain, N. Y., Health Officer
 Joseph W. Belser, M.D., East Greenbush, N. Y., Acting Health Officer
 Lewis E. Bratt, M.D., Akron, N. Y., Health Officer
 Robert Brittain, M.D., Downsville, N. Y., Health Officer
 Marshall W. Brown, M.D., 73 W. Main St., Babylon, N. Y., Health Officer
 Ralph Frazier, M.D., Bergen, N. Y., Health Officer
 Donald B. Glezen, M.D., Cincinnati, N. Y., Health Officer
 Norman G. Gridley, M.D., 404 Main St., Horseheads, N. Y., Health Officer
 Francois Guimont, M.D., Pointe Basse, Iles de la Madeleine, P. Que., Canada, Medical Officer of Health
 Joseph Gutfreund, M.D., Eldred, N. Y., Health Officer
 Clifford H. Harville, M.D., 88 N. Main St., Warsaw, N. Y., Health Officer
 Aaron I. Levis, M.D., Madison, N. Y., Health Officer
 Louis A. Luttge, M.D., 42 Central Blvd., Central Park, L. I., N. Y., Assistant, Social Hygiene Clinic, Nassau County Public Health Commission; Taking Health Officers Course
 George A. McQuilkin, M.D., Varysburg, N. Y., Health Officer
 Alvia R. Morrow, M.D., Cazenovia, N. Y., Health Officer
 Ray P. Moyer, M.D., 620 City-County Bldg., Pittsburgh, Pa., Director, Pittsburgh Department of Public Health
 William D. Peckham, M.D., 1207 State St., Utica, N. Y., Health Officer, Consolidated Health District of Marcy and Floyd
 Paul S. Persons, M.D., 22 E. Main St., Ripley, N. Y., Health Officer
 Robert S. Pratt, 5725 Main St., Williamsville, N. Y., Taking Health Officers Course (Assoc.)
 Burton L. Rockwell, M.D., Oriskany Falls, N. Y., Health Officer, Augusta Marshall Townships
 Baylis F. Sloan, M.D., Walhalla, S. C., Medical Director, Oconee County Health Department
 Herbert B. Smith, M.D., 143 Pine St., Corning, N. Y., Commissioner of Health
 Claude H. Vadney, M.D., Lyons Falls, N. Y., Health Officer

Laboratory Section

Dr. Tomas Padro y Alvarez, Heredia alta 15, Stgo de Cuba, Orte, Cuba, Chief Chemist of the Laboratories of the Sanatorium of the Spanish Colony in Central Gallego
 Dr. Leasure Kline Darbaker, 424 Franklin Ave., Pittsburgh, Pa., Professor of Microbiology, Pittsburgh College Pharmacy
 Nelle M. Fishel, B.S., City Hall, Des Moines, Ia., City Bacteriologist
 Clifford D. Gallagher, M.D., Faxon Hospital, Utica, N. Y., Director of Hospital Laboratory
 Margaret Hotchkiss, Ph.D., 146 Halsey St., Brooklyn, N. Y., Instructor in Bacteriology, Public Health, etc., N. Y. Homeopathic Medical College and Flower Hospital
 George Ives, M.D., 3720 Washington Blvd., St. Louis, Mo., Clinical Pathologist
 Alfred W. Jackson, M.D., D.V.M., 124 Main St., Albion, N. Y., Health Officer
 Samuel T. Lindsay, M.D., St. Mary's Hospital, Rochester, N. Y., Laboratory Director
 Howard C. Maffitt, 522 Eleventh St., Des Moines, Ia., Consulting Chemist
 Maurice R. Moore, M.D., W. W. Backus Hospital, Norwich, Conn., Director of Laboratory
 Theodore A. Olson, B.S., State Dept. of Health, Div. of Sanitation, Minneapolis, Minn., Biologist
 Clarence C. Ruchhoft, B.S., 845 S. Wabash Ave., Chicago, Ill., Bacteriologist, Sanitary District
 Joseph I. Schleifstein, M.D., 785 Park Ave., Albany, N. Y., Associate Diagnostic Pathologist, Div. of Laboratories and Research, State Department of Health
 Gustav Selbach, M.D., 66 Elizabeth St., Dansville, N. Y., Director, Livingston County Laboratory
 Harold L. Smith, B.A., 217 Park Place, Ash-tabula, O., Bacteriologist
 Geral A. Vacha, M.S., Rm. 527, State Office Bldg., St. Paul, Minn., State Bacteriologist

Public Health Engineering Section

Roy M. Harris, B.S., 1504 Alaska Bldg., Seattle, Wash., P. H. Engineer, State Department of Health
 Eugene O. Leonard, Ph.G., Department of Health, Pocatello, Idaho, City Chemist
 Gustavo Noguera S., Apartado 1509, Bogota, Columbia, S. A., Chief Engineer, National Public Health Department (Assoc.)

Carlos B. Ruiz, Apartado No. 76, Torreon, Mexico, Manager, Torreon Water Works
Lynn M. Thatcher, 126 State Capitol, Salt Lake City, Utah, State Sanitary Engineer

Public Health Nursing Section

Luella Tanner, R.N., P.H.N., Hoolehua, Molokai, T. H., Public Health Nurse
Ruth Tappan, R.N., 225 N. Washington Ave., Battle Creek, Mich., Director, Crippled Children's Service, W. K. Kellogg Foundation
Cora Warrant, R.N., 130 Spring St., Rochester, N. Y., Director, Public Health Nursing Association

Industrial Hygiene Section

Clarence E. Ralston, Pittsburgh Plate Glass Co., Grant Bldg., Pittsburgh, Pa., Safety Director (Assoc.)
Martin E. Tyrrell, M.D., Transit Road, Depew, N. Y., Health Officer and Industrial Physician

Child Hygiene Section

LABORATORY

STUDIES WITH STANDARD AGAR AS EMPLOYED IN MILK CONTROL WORK*

C. S. BOWERS AND G. J. HUCKER

Laboratory of the Board of Health, New Britain, Conn.; Agricultural Experiment Station, Geneva, N. Y.

I. A COMPARATIVE STUDY OF YEAST AND BEEF EXTRACT MEDIA

YEAST extract has been reported to be excellent for the cultivation of many different types of organisms which either do not develop generally on standard medium or whose colonies are so minute that they are observed with difficulty.

In order to determine whether the substitution of yeast extract for beef extract in standard medium would increase its efficiency when used to estimate the number of bacteria in milk, a series of 514 samples of raw and pasteurized milk were plated upon standard medium, standard medium with yeast extract substituted for beef extract, and plain peptone agar, and incubated at standard temperature. These samples were representative of the usual sources from which milk control laboratories receive samples; that is, directly from cows, from milk receiving stations, from different points in pasteurizing plant operation, from delivery vehicles, and from retail stores. In addition, they were representative samples of various grades of milk both raw and pasteurized.

The yeast extract counts of 373 raw

milk samples were 9 per cent lower than those secured with standard agar, while the counts of 141 pasteurized milk samples were 20 per cent below the standard count. Standard medium produced a maximum plate count from 65 per cent of all samples included in the study while the yeast medium yielded the highest count in 25 per cent.

Slightly larger colonies developed in many instances on the yeast extract medium but this characteristic was not constant, since organisms which produced the pin-point type of colony were slightly larger on the yeast medium in some cases but in others the colonies were more minute than on the standard medium.

It is concluded that the advantages of yeast extract for the plating of fluid milk are insufficient to warrant its use as a substitute for beef extract in the standard medium.

II. THE EFFECT OF A MODIFIED STANDARD MEDIUM FOR THE DETERMINATION OF THE BACTERIAL FLORA OF MILK

Many workers engaged in the sanitary control of milk supplies have criticised standard medium because it has often failed to indicate the presence of certain types of organisms found in milk. As a result a plate count has frequently been secured which did not

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

Approved by the Director of the New York State Agricultural Experiment Station for publication as *Journal Series No. 39*.

give an indication of the actual number or types of bacteria present. The results of the previous study confirmed the observation of others that yeast extract was more beneficial to some organisms than it was to others. As a consequence an additional investigation was begun in the Division of Bacteriology at the Agricultural Experiment Station in Geneva, N. Y., to ascertain whether the efficiency of modified standard medium could be enhanced by the addition of yeast extract, and to determine further if the inclusion of yeast extract in media was responsible for increased size of colonies.

In order to observe what effect the use of certain modifications of standard medium would have upon the number and types of bacteria which would develop from milk, the plate counts from a series of 27 normal and 23 abnormal raw and pasteurized milk samples were secured by employing standard agar with and without dextrose, yeast extract agar with and without dextrose, plain peptone agar, beef and yeast extract agar with and without peptone, and Difco yeast dextrose agar which contained beef extract, yeast extract, tryptophane broth, peptone and dextrose.

Samples of raw milk which were considered normal were composite samples from a herd at the Agricultural Experiment Station, from producers supplying milk to a pasteurizing plant in Geneva, N. Y., and from a receiving station at Oxford, N. Y. Some of the abnormal raw milk samples were secured from cows segregated from the station herd because of suspected mastitis, and others were from different samples of raw milk which were collected immediately after the evening milking and stored at 25° C. overnight.

Samples of normal pasteurized milk were taken from the plant at Geneva and others were received from New York City and Boston, Mass. Samples of pasteurized milk which were held at

10° C. for 12 days and pasteurized milk samples which were suspected of containing thermophilic bacteria were considered as abnormal pasteurized milk samples. Incubation of plates was at 32° C. and 37° C. for 48 ± 4 hours.

Difco yeast dextrose agar allowed the development of the greatest number of colonies in 45 per cent of all samples at standard incubation and in 48 per cent of all samples at 32° C. In no instance did standard medium give a maximum plate count. The addition of dextrose to standard medium resulted in higher plate counts than were secured with yeast extract plus dextrose, and the colony size was increased more by the addition of dextrose than by the addition of yeast extract to standard medium.

In the vast majority of cases all media were conducive to higher counts when plates were incubated at 32° C. than at standard temperature. Standard medium plate counts were higher at 32° C. than at 37° C. in 86 per cent of the cases. However, the effect of the difference in temperature of incubation upon the magnitude of the count was less appreciable when yeast extract was added to standard medium; only 56 per cent of the standard medium plus yeast extract counts were higher at 32° C. than at 37° C. Counts secured with Difco yeast dextrose medium and incubated at 32° C. were approximately 4 times as great as those secured with standard medium at standard temperature.

In the authors' opinion too little consideration has been given in the past to the ease with which the number of colonies appearing on a plate can be counted. Standard agar is a gross offender in this respect and it was exceedingly noticeable in the present study, since all media, with the exception of plain peptone in a few instances, yielded colonies which were larger than those on standard agar. Usually these

colonies could be counted with ease by the naked eye and without the aid of artificial illumination. On the other hand, it is quite apparent that any successful attempt to do away with the troublesome problem of minute colonies must also result in higher plate counts. The problem seems to be one which is due to unsatisfactory nutriment more than one of time and temperature.

From the results of this study it is concluded that:

Yeast extract is not superior to beef extract for plating both raw and pasteurized milk.

The combination of yeast and beef extract in a medium for milk plating

is more efficient than the use of either one separately.

Neither yeast extract nor beef extract materially increases the number of colonies over plain peptone agar.

The addition of a fermentable carbohydrate to standard medium generally causes an appreciable increase in count and colony size.

The addition of glucose to standard medium increases the count approximately $2\frac{1}{2}$ times more than the addition of yeast extract.

Counts obtained with the present standard temperature may give a false impression of the actual number of bacteria present in milk.

THE MECHANISM OF BACTERIOPHAGE LYSIS*

J. BRONFENBRENNER, PH.D., F.A.P.H.A. (*Life Member*)

Washington University Medical School, St. Louis, Mo.

ON the basis of experimental evidence secured in the study of the mechanism of lysis in the presence of moderate initial concentrations of bacteriophage, the conclusion was reached that progressive disappearance of organisms during the period of phage regeneration (and before its concentration has reached the maximum level) is due to bursting. This is brought about through an increase in the rate of cellular metabolism, which results in the increase in osmotic pressure and imbibition of water, leading to swelling and finally to disruption of cells.

However, if the concentration of phage is initially at a limiting level, or when it approaches this level as the result of regeneration, the susceptible bacteria are killed and subsequently

digested without undergoing the changes just described.

By setting up a competition for water between the bacteria and the medium (as in the case of 4 per cent agar, for instance), both the swelling and lysis of bacteria are prevented. However, if to such a medium is added 4-5 per cent of urea, both the swelling and the lysis of bacteria again take place.

On the other hand, while increase in competition for water prevents both the swelling and lysis of bacteria, the effects of the presence of phage are not totally abolished. Indeed, bacteria which come in contact with phage under these conditions still exhibit heightened metabolic activity, as indicated by marked increase in the rate of multiplication. While this effect is particularly marked under the conditions which preclude lysis, the growth-promoting effect of phage can be detected also under the

* Abstract of paper read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting at Indianapolis, Ind., October 11, 1933.

ordinary conditions when the lysis is not inhibited, particularly on ordinary solid media. Moreover, if the initial concentration of phage is kept sufficiently low, so that the obscuring effect of concomitant lysis of progressively increasing numbers of bacteria is minimized, it is possible to detect this growth-promoting effect in ordinary broth cultures, both in terms of turbidity changes of the whole culture and by count of surviving bacteria.

Thus it appears that the primary

effect of phage consists in the stimulation of bacterial metabolism. This effect can be elicited under all conditions employed in these experiments, irrespective of whether lysis takes place or not.

The lysis proper is a secondary phenomenon, which occurs as a direct result of imbibition of water by the bacteria following the osmotic changes set up by the increased metabolism. Whenever this imbibition of water is interfered with, the lysis is prevented.

VITAL STATISTICS

Birth Rates and Illegitimate Births in Germany and Other European Countries—In 1932 Germany, Italy, and Poland had a marked decline in the birth rate. In the German reich the number of living births receded by 53,600. In Italy the number of living births was 34,150 fewer than in 1931, so that in 1932 the birth rate for Italy was only 23.8 per 1,000, as compared with 24.9 per 1,000 the previous year and 26.7 in 1930. In Poland in 1931, 50,000 fewer births were recorded, and in 1932 there was a further decline of nearly 34,000; the birth rate of Poland dropped, over the 2-year period, from 32.3 (1930) to 28.7 per 1,000 population. In the remaining countries of western, central, and northern Europe the decline in the birth rate ranged from 0.2 to 0.7 per 1,000. France had a decline in its birth rate of only 0.2 per 1,000. In Sweden and Hungary the birth rate was only 0.2 and 0.3 per 1,000 population, respectively, lower than in 1931, whereas Great Britain and Czechoslovakia showed a decline of 0.5 and Austria a drop of 0.7 per 1,000. Unchanged

birth rates were recorded in the Netherlands and in Switzerland.

The countries of lowest birth rates at present are the German reich, Austria, Sweden, and Great Britain, with birth rates ranging from 14.5 to 15.8 per 1,000. France (with a birth rate of 17.2), Belgium (18.1), and Switzerland (16.7) have in recent years passed out of the group of nations with the lowest birth rates. The birth rates in Norway (16.7), Denmark (18.0), and Finland (19.5), together with Lithuania and Estonia, range around that of France and in some cases exceed it. In countries bordering on this area, limitation of births is making further progress, particularly in Czechoslovakia, Hungary and Italy, which countries report, in contrast to former high rates, birth rates of from 21 to 24 per 1,000, which are lower than the birth rate of the German reich in 1923 (26.9). The birth rates in the countries of the Iberian peninsula (28.3 and 30.7) and in eastern and southeastern Europe are still high. There appears to be evidence, however, that the demographic pressure of the Slavic races of the East

will in the near future lose considerable of its force. It may be added that in 1932 the population of Japan increased by 1,007,868 (in 1931, by 861,534).

The percentage of illegitimate births in Germany (12.1) is exceeded by that of only one European country (Sweden with a percentage of 16.1). The corresponding percentage in Greece is 1.4; Bulgaria, 4.0; Great Britain, 4.6; Italy, 4.9; Norway, 7.1; France, 8.4; and Denmark and Czechoslovakia, 10.7.—*J.A.M.A.* 102:308 (Jan. 27), 1934.

Health Conditions in New York State, 1933—In attempting to evaluate the effects of the fourth year of the intense economic depression upon the health of the people of New York State, it is essential to realize that vital statistics, or to use the more comprehensive term, demography, can give us only a partial picture of the situation. In 1933, as could be anticipated, the downward trend of the birth rate continued. At the same time, the marriage rate has risen about the minimum for the preceding year.

The general death rate of 11.2 per 1,000 population, however, is the lowest ever recorded in the state. The significance of this fact is likely to be misunderstood or misinterpreted. Some superficial, and one might say callous observers have stated that the drop in the death rate indicates the beneficent effects of economic deprivation. This, of course, is not true. All that one can say is that official and private aid has not permitted the workers who were thrown out of their jobs to starve to death; that official and private health agencies have been able, in the face of increasing difficulties, to carry on and even to expand their preventive and curative activities.

The number of marriages recorded in

the entire state in 1933 was 106,295, an increase of more than 5,000 over the preceding year; the marriage rate was 16.0 per 1,000 population as compared with 15.5 in 1932. The 1933 birth rate of the entire state was 14.0, the lowest ever recorded. The number of births was less than in 1932 by almost 13,000. With but few exceptions, the birth rate of the state has been moving downward since 1914 when the maximum figure of 24.6 was recorded. In the brief interval 1927–1933 it has dropped more than 25 per cent—from 19.0 to the present minimum of 14.0.

The rate of infant mortality, 54 deaths under 1 year per 1,000 live births, was practically equal to the minimum recorded in 1932. The disquieting rise in maternal mortality, which was first noted in 1930, continued; the 1933 rate, 60 deaths per 10,000 total births, was the highest in 15 years. The increase above the rate of 1932 was due entirely to a rise in the mortality from puerperal sepsis, the rate for the former year being 18.5 and the 1933 rate, 19.9.

Death rates from several important causes established new minimums for all years. The rates from whooping cough (2.2 per 100,000 population) and diphtheria (1.1) have never been lower; the latter was about half of the previous minimum of 2.1 registered in 1932. The pneumonia death rate (91.2) has never been lower; rates below 100 were recorded only twice before, in 1921 and in 1932.

Of the diseases that are most directly influenced by economic want, tuberculosis undoubtedly is one of prime importance, and yet its death rate has dropped to the lowest point in the history of the state (59.0)—a reduction of more than 50 per cent since 1920.

In view of the nation-wide attention focused upon lethargic encephalitis by the St. Louis epidemic, it is interesting

to note that the mortality from this cause in New York State (0.6) has never been lower.

Compared with 1932, decreases were recorded in mortality from scarlet fever (1.7) and diseases of the heart (289.6). The mortality from alcoholism (4.7) has not been lower since 1922, and the rates of suicide (17.4) and homicide (5.3) were the lowest since 1929. The death rate from fatal accidents (67.8) has been lower only once. Noteworthy in this group is the reduction of fatal automobile accidents,

the rate (21.1) being the lowest since 1926; the highest rate ever recorded in the state was 25.5 in 1929.

Among the more important negative facts is the rise of the death rates from cancer (127.5) and diabetes (30.3) to new maximums; the measles death rate (2.5) was the highest in 5 years; there was also a slight increase in the mortality from diarrhea and enteritis among children under 2 years of age, the rate being 6.8 compared with the minimum of 6.5 in 1932.—*New York State Health News*. 11:29–30 (Feb. 19), 1934.

INDUSTRIAL HYGIENE

Some Cases of Carbon Tetrachloride Poisoning in Connection with Dry Shampooing and Dry Cleaning with a Survey of the Use and Action of the Substance—The action of carbon tetrachloride on the human organism is discussed. Carbon tetrachloride has a protoplasmic-injuring action with the same narcotic potency as chloroform. Occupational carbon tetrachloride intoxication presents a rather characteristic picture which consists of a headache accompanied by nausea and vomiting, with a subsequent development of hepatitis or nephritis with their characteristic symptoms.

Several uses of carbon tetrachloride and the accompanying dangers are discussed. This substance is used largely in place of benzine for the removal of grease, extraction of fats, solvent for crude rubber, fire extinguishers, and as an anthelmintic drug. It has also found a popular use in Denmark in connection with shampooing. Several histories of carbon tetrachloride intoxication from this as from other occupational sources are given and discussed.

The author feels that carbon tetra-

chloride can be used more advantageously than benzine as a solvent if the public can be instructed as to the toxicity of the substance and methods of handling it without danger to life and health. Carbon tetrachloride would be, however, prohibited as a shampoo.—Knud O. Moller, *J. Indust. Hyg.*, XV, 6:418–431 (Nov.), 1933.

L. G.

Health Aspects of Radium Dial Painting. III. Measurements of Radioactivity in Workers—This study considers the amount of radioactive substance found in the living human body by the measurement of radioactivity in the workers employed in the radium dial painting industry. Gamma ray, radon and thoron determinations were made by various electroscopic tests which are described in detail. The average gamma micrograms of radium readings are as follows: radium transfer press operators, +0.16; painters from +0.23 to +1.70; and dusters, +1.03. The probable error of measurement in the tests was about 0.3 micrograms.

The results of the study showed that

high gamma-ray concentrations were confirmed by high radon or thoron readings, or both, indicating that in general individuals giving a high gamma-ray reading are radioactive. There is little evidence to believe that the radium dial painters would become radioactive during the first year of service, but after the first year there seems to be definite evidence of the accumulation of radioactive material. There was, however, little correlation between radioactivity and length of exposure. Other factors such as degree of exposure, personal cleanliness, working conditions (factory housekeeping), and individual susceptibility were of greater importance. There was definite indication that the accumulation of radium in the body of the workers was associated with the degree of radioactivity of the atmospheric dust to which they were exposed.

In order to have some standard of comparison electroscopic determinations of a known quantity of radium emanation distributed in a cadaver were made. Radon seed was injected into the body and measurements were taken with the cadaver arranged in an identical position as when determinations were made on workers. Finally the sensitivity of the electroscope was checked against a 10 mg. standard of radium.—James E. Ives, Fred L. Knowles, and Rollo H. Britten, *J. Indust. Hyg.*, XV, 6:433-446 (Nov.), 1933. L. G.

Health Aspects of Radium Dial Painting. IV. Medical and Dental Phases—This paper concludes the report of an investigation of the radium dial painting industry by the U. S. Public Health Service, and deals with the medical and dental phases of the problem. The results of this study indicate no correlation between radioactivity or exposure to radium and

blood pressure changes, radium burns, or change in finger prints. Slight reduction in the red cells count showed 4.3 million R.B.C. per c.c. for 196 women radium workers as compared with 4.5 million per c.c. for the 31 controls, and in the hemoglobin determination which gave an average of 13.2 gm. per 100 c.c. of blood for 196 women radium workers, and 14.0 gm. per 100 c.c. for the 31 controls. The change in the total white cell count was not significant.

Examination of mouth, teeth, and bone showed no stomatitis such as might be associated with metallic poisoning but disclosed focal atrophy and focal sclerosis. There was definite relation between these dental findings and exposure to radium. Workers having more than 4 micrograms of radium showed bone changes.—Louis Schwartz, F. C. Makepeace and H. T. Dean, *J. Indust. Hyg.*, XV, 6:447-455 (Nov.), 1933. L. G.

Experimental Inhalation of Bituminous Coal Dust and Its Effects Upon Primary Tuberculosis Infection in Guinea Pigs—This study was carried out in an industrial plant where experimental animals were exposed to an average concentration of 84 million particles of coal dust under 10 microns in diameter per cu. ft. of air. The coal was characterized by a high carbon content and a relatively small amount of volatile matter and silica. The animals were divided into five small groups which consisted of: (1) normal guinea pigs exposed for varying intervals to the inhalation of soft coal dust to produce maximal reaction in their lungs; (2) guinea pigs infected with attenuated tubercle bacilli 10 days before initial dust exposure; (3) presumably uninfected anthracotic guinea pigs which were infected by the inhalation of attenuated tubercle bacilli 115

days after the completion of 1 year and 9 months' dust exposure; (4) guinea pigs similar to the preceding group except that the animals were infected by the inhalation of a more recently isolated strain (H 60) of human tubercle bacilli of moderate virulence; and (5) animals infected with virulent tubercle bacilli 10 days previous to exposure in the plant.

The results of the experiments seemed to indicate the following:

(1) soft coal did not penetrate the lungs as much as quartz or carborundum. There is little cellular fibrosis in the connective tissue sheaths of bronchi and blood vessels but rather a more marked fibrotic action in the medulla of the mediastinal lymph nodes. The general nature of the reaction is comparable to that observed in the human lung; (2) soft coal dust is eliminated rather slowly from the lungs of guinea pigs (three years after discontinuing an exposure 2 years in duration, subpleural pigmentation was still marked); (3) there may be some protective action by inhaled bituminous coal dust against the development of a tuberculous infection.—Leroy U. Gardner, Donald E. Cummings and Gerald S. Dowd, *J. Indust. Hyg.*, XV, 6:456-465 (Nov.), 1933. L. G.

Time Limitation in Compensation for Industrial Diseases—The difficulties experienced in the application of a time limit in compensation cases for occupational diseases in New York State and Minnesota is discussed. The phraseology of the law is such that the time limit for compensation claims provides a difficult medico-legal problem. This is particularly true when the industrial diseases are cumulative in character.

The author advocates the adoption of a time limit in industrial compensation laws which is, in one way or an-

other, specifically related to the time of leaving the employment. The time limitation would then be more or less determinable and would avoid controversies experienced by the compensation legislation of New York State and Minnesota, which bases the time limitation upon the date when an occupational disease is "contracted."—May R. Mayers, *J. Indust. Hyg.*, XV, 6:465-472 (Nov.), 1933. L. G.

Bureau of Mines Approved Devices for Respiratory Protection—

This article deals with the activities of the Bureau of Mines in preparing minimum requirements for safety and durability of respiratory devices, and devising tests to ascertain the ability of the equipment to meet the requirements before giving approval to them. Specifications and tests have been prepared for self-contained oxygen breathing apparatus, canister gas masks and for hose masks. Any equipment which has been granted an approval by the Bureau of Mines is required to maintain approval standards. The Bureau of Mines has done much to stimulate the production of improved respiratory devices as well as to protect the consumer from faulty and unsatisfactory devices for respiratory protection. A selected list of references to respiratory devices is given.—W. P. Yant, *J. Indust. Hyg.*, XV, 6:473-480 (Nov.), 1933. L. G.

Diurnal and Seasonal Variations in the Small Ion Content of Outdoor and Indoor Air—This is a study of the ionic content of outdoor and indoor air conducted at the Harvard School of Public Health at Boston, Mass. Daily ion counts (small ions) were made over a period of 3 years, between May, 1930, and May, 1933.

The results of the study indicate a definite diurnal and seasonal variation

in the ionic content of the atmosphere depending largely upon local and general meteorological conditions. Daily peaks occurred shortly after mid-day and mid-night, and the low points occurred between 6 and 10 p.m., and 4 and 8 a.m. There was a distinct seasonal maximum during the summer months and a minimum during the winter months.

Interdiurnal changes of temperature and humidity appeared to be the most important climatic factor affecting the small ion content of outdoor air. A drop in the interdiurnal temperature and humidity was preceded or accompanied by a sharp rise in the ion content of the air and *vice versa*, provided that the drop or rise in temperature and humidity did not continue for more than 2 days.

Cloudiness, high humidities and precipitation seemed to influence the ionic content of the atmosphere. Significant reductions in the number of small ions were noted at all seasons. Heavy precipitation resulted in a considerable increase in negative ions from the Lenard effect.

It was found that the concentration of small ions in indoor air was considerably lower than that in the outdoor air in the winter. In the summer the reverse held true. Persistent bad weather tended to equalize the indoor and outdoor ion content.—C. P. Yaglou and L. C. Benjamin, *Heating, Piping & Air Cond.*, 6, 1:25-32 (Jan.), 1934.

The Therapeutic Uses of Polarized Air—The ionic content of the atmosphere is being recognized as appearing to be of great medical importance. This study presents the results of polarized air treatment of 84 patients to whom 1,200 treatments were administered. Each treatment extended over a period of 15 minutes and the doses administered varied from 10 to 20 million ions per c.c. of air. The results of the treatments are as follows:

Diagnosis	Improvement	Moderate Improvement	No Improvement	Patients 1-3 Treatments
Sinusitis	6	13	14	16
Asthma	2	8	5	6
Ess. Hypertension	4	1	1	2
Vasomotor Rhinitis	3	—	—	2
Atrophic Rhinitis	—	—	1	—

While the experimental series is too small to permit any definite conclusions, the author feels that this procedure shows therapeutic possibilities in certain types of sinusitis, asthma, essential hypertension, and vasomotor rhinitis.

There is a general discussion of ions with particular reference to the type, size, velocity and distribution of ions in the atmosphere. Methods of producing ions are briefly discussed and a description of the Dessauer Ionization Apparatus is given.—William Bierman, *Arch. Phys. Therapy, X-Ray, Radium*, XIV:133-137 (Mar.), 1933. L. G.

"Nose-Opening" Rays—This study repeats the work of Leonard Hill, who claims that all dark sources of heat are "nose-shutters," and that bright, incandescent sources of heat act as "nose-openers." Blind persons were chosen as subjects to rule out certain psychic factors which Hill claimed were acting as inhibitors of the phenomena. The subjects were seated in a chair screened from drafts and light, by a shelter, and exposed to a bright source and then to a dark source of heat for a certain interval. Inspiratory and respiratory pressure were recorded by a sensitive manometer of the aneroid type which was connected to one nostril.

The results of the study failed to confirm Hill's observations and indicated that the "nose-closing" is probably caused by any rapid warming of the skin and that it is not dependent upon any particular quality of radiation. Screening from the heat source or sponging a small area of the skin with

cold water gave immediate relief in the experiments.—A. F. Dufton and T. Bedford, *J. Hyg.*, XXXIII, 4:476-484 (Nov.), 1933. L. G.

The Mortality Experience of an Occupational Group Exposed to Silica Dust Compared with that of the General Population and an Occupational Group Exposed to Dust Not Containing Silica—This is a very interesting statistical analysis of the mortality experience of an occupational group exposed to silica compared with that of a general or standard population and an occupational group exposed to dust not containing silica. By standardizing the deaths it was found that the comparative mortality figures for all causes and all ages (20-65) were 1,000 for the standard population, 1,984 for the silica group, and 967 for the

non-silica group respectively. Comparative mortality experienced in the silica group for 23 causes or cause groups, showed only 3 causes (diabetes, appendicitis, and other diseases of the digestive tract) with mortality not significantly different from that of the standard population. Very high mortality (over double that of the standard population) were noted due to pulmonary tuberculosis, other tuberculosis, chronic rheumatism, bronchitis, chronic interstitial pneumonia, other diseases of the respiratory system, and hernia.

In the non-silica occupational group mortality for influenza, pulmonary tuberculosis, bronchitis, chronic interstitial pneumonia, and other diseases of the respiratory system was higher than that of the general population.—Edgar L. Collis and G. Yule, *J. Indust. Hyg.*, XV, 6:395-417 (Nov.), 1933. L. G.

CHILD HYGIENE

MATERNAL AND CHILD WELFARE WORK IN RUSSIA

TWO recent publications^{1, 2} have been received from Russia which set forth an interesting and unique program for the protection of motherhood and childhood under way in the Soviet Union. The philosophy and activities of the socialist state as related to maternity and child hygiene are clearly portrayed.

The protection of motherhood and childhood is one of the most important problems of the Commissariat of Public Health. It occupies a special place in the social policy of the Soviet State as a whole. The importance of this problem is immediately connected with the rôle and place which the working woman of the land of Soviets occupies in state construction, in social life and in industry in all its stages and forms, as one participating in all its activities with a perfect equality of rights.

The principal points which characterize the Soviet code of laws for the protection of maternity are:

1. The woman working in a factory who is engaged in physical labor is released from all work for a period of 8 weeks before and 8 weeks after her confinement, with full wages. If she is an employee or worker in a mental profession her leave is 6 weeks before and 6 weeks after her confinement.

2. A woman cannot be discharged during her pregnancy and motherhood leave. She must be reaccepted to her work after her leave.

3. The nursing mother in addition to the usual intervals of rest during work is entitled to no less than half an hour every 3½ hours of work. These periods of interruption in her work are counted as working time.

4. The pregnant or nursing mother cannot be sent on missions. No overtime work or night work is allowed for pregnant and nursing mothers. The pregnant woman has the right to receive a railway ticket or necessary information in Soviet offices out of turn.

5. In U.S.S.R. the mother is made economically independent by being insured in the State Social Insurance Organization. It

is the state organization and not the working woman that pays this fee in its entirety.

The social insurance of motherhood is carried out by giving the woman help in the following cases:

1. For pregnancy and delivery
2. For the infant's feeding, for his care and for nursing him during illness
3. For free medical care

The assistance for pregnancy and motherhood is paid to those insured during the full time of their leave according to clause 132 in the measure of their full wages during this period.

4. Those insured and their wives in the case of child birth receive additional assistance granted but once for the care of the newborn. This assistance is equal to the average monthly wages for workers of the given locality. Another sum for the child's food equal to the fourth of the average monthly wages of the given locality is paid every month during 9 months beginning from the day of the child's birth.

PRESCHOOL INSTITUTIONS

Preschool education in Russia was one of the weakest links in public education before the Revolution. In 1913 there were only about 200 institutions for it in the whole country.

Immediately after the Revolution, a rapid growth of kindergartens and other preschool institutions set in; they numbered thousands even in the first years of Soviet power, which were those of civil war. But the growth of national economy in town and country, the entering upon the reconstructive period called for a still greater extension of the preschool net as well as of that of creches.

The growth of preschool education which the first Five-Year Plan had in view has not only been achieved, but has been carried out in an eight- or nine-fold measure—thus, by the end of the first Five-Year Plan (1932), 500,000 children were to have been enrolled in the R.S.F.S.R., whereas in reality their number exceeded 4 millions.

By the end of the second Five-Year Plan period in 1937, the number of children benefiting by the service of educational in-

stitutions must reach in the R.S.F.S.R. a figure of 10.5 millions.

In progressive districts of the Union an enrollment of all preschool children has nearly been completed. In Moscow even by the end of the year 1932 preschool institutions had absorbed 90 per cent of all the children of workers, and in the Ural industrial centers—75 per cent.

Among the public organizations rendering help in the work of education and of improvement of sanitary conditions for preschool children a prominent place has been taken by the preschool coöperation, which has considerably grown of late. Many millions of parents have been drawn into the work of preschool education, especially mothers, who take this task to heart and consider it to be of the greatest importance. It is to public assistance and support that the rapid growth of preschool education is due. In the year 1932 upwards of 70,000 kindergarten teachers were trained at courses of short duration, and in 1933 upwards of 80,000 will be trained in the R.S.F.S.R. alone. . . .

Preschool institutions are of varied types including:

- (a) The kindergartens without boarders
- (b) The kindergartens with boarding section
- (c) The children's rooms attached to clubs
- (d) The children's rooms attached to the schools for adults (for the mothers who are studying)
- (e) Children's playgrounds out of town and in town: in courtyards, on boulevards, in green squares, in parks
- (f) Children's homes for orphan preschool children. . . .

The time which the child spends in the preschool institution varies according to the nature of the occupation of its parents, but as a rule it is at least 7-8 hours and sometimes 10-12 hours a day. This is especially true as regards kindergartens attached to enterprises where women are mainly employed. A large number of dormitories are now attached to the kindergartens. The child is taken care of both during the day and at night time. In Moscow in 1932, of 65,000 children in kindergartens 19,000 were boarders. Their number more than doubled in the course of 6 months. . . .

The great tasks with which the country is confronted in the second Five-Year Plan has greatly enhanced the political importance of the further development of preschool education.

The rapid growth of the network of preschool institutions during the last few years, the attention paid to them by proletarian

organizations, the mobilization of local resources of the country, of the population itself for the construction of kindergartens and playgrounds, enable us within the next few years to realize for the first time in the world the task of introducing universal preschool education in the land of the Soviets.

By the end of the second Five-Year Plan all children from 3 to 7 will have been embraced by preschool education.

We have already begun to tackle this task.

In 1932, 85,000 new preschool teachers were trained. The stationary pedagogical school alone cannot in the near future cope with this task. The main work will have to be done by means of short-term courses which are organized all over the country (3, 5 and 8-months courses). However, the stationary institutions will gradually increase in number, until they will fully supplant the short-term courses.

The main task at the present time is to select the best of the students after their completion of the short-term courses and give them a thorough training. The main task will be to show them the work of model kindergartens, to acquaint them with the achievements of the more advanced and successful ones. Therefore a network of model preschool institutions and district pedagogical cabinets is being set up. Each district, as a rule, has not only a preschool inspector but also a "methodist" (specialist) introducing the more up-to-date methods. Many new advance courses for preschool workers are set up, as well as pedagogical consultative departments for conducting work with the parents.

Special stress is being now laid on the quality of the work. This is the surest method of guaranteeing continued successes.

The quantitative increase in and the qualitative improvement of preschool institutions are closely bound up with each other and together they constitute the great task of bringing up the children of the Soviet Union in the communist spirit.

The broad masses of the population and the social organizations of the U.S.S.R. are all actively participating in creating ever more and more kindergartens, in their qualitative improvement, in bringing about universal preschool education.

EDUCATION AND PUBLICITY*

THE AUDIT.

SUPPLEMENTARY to the main elements of a social educational publicity program should be a merciless personal audit of the finished project. After the returns are all in—when the last meeting has been held, the final distribution of printed matter made, and all activities of the immediate effort have been recorded as history—is the time to put yourself and your methods through the third degree.

Accept with becoming modesty the compliments of friends and well wishers. Then seek your chronic kicker and solicit him to unburden himself. He may be inaccurate and will surely be unfair, but out of it you may get some leads for further examination in seeking how better to plan and administer the next time.—Elements of a Social Publicity Program. *Proceedings of National Conference of Social Work, 1920.*

When the Health Officer Is "Overpaid"—Some people, according to *Health News*, New York State Dept. of Health, argue that health officers do too little to earn their salaries:

. . . The trouble is that local officials, usually town supervisors, who start these movements have no idea what their health officers are doing. This is largely the fault of the health officers themselves. If every health officer would regularly make to his local officials an *interesting and readable* report and publish the report, or an *interesting* summary in a local paper, it would do much to put an end to such movements.

"Health Education in an American City"—This is not a review of the new book by Louise Franklin Bache. That function will be fulfilled in due season in the regular book review section of the *Journal*. This is merely an appreciation of what the book is, and an attempt at describing what the book is not.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

We have long needed a book of this type—a review of what an effective health department actually has done, directly and in coöperation with other local agencies. We wish that the book could have been larger, so as to cover in equal detail the individual health education activities of the various coöperating health and other agencies in Syracuse. There is a place on the bookshelf for that sort of book.

This book is not a manual on health education, but it has some of the valuable characteristics of such a volume. It tells of activities carried on and materials prepared and used. In recording all this nearly every page gives some glimpse of why something was done, why it seemed to be successful, why it failed or was unsatisfactory.

How could so much be done in 5 years, so much of such a degree of excellence? The answer is easy. There was the sympathetic sponsorship of the Milbank Fund and the State Charities Aid Association; an enlightened health department policy,

and an understanding health officer; a generous, but not lavish, budget; an unusually equipped director of health education, and an exceptional team of specialists on the department staff, and the staff of the local public health association. Has any other city had such a team working under such favorable conditions?

In *A City Set On A Hill*, Professor Winslow tells how important is the adequately prepared director of health education. The yearly budget varied from \$11,477 to \$13,378, or as stated by Professor Winslow,

5.4 cents per capita, which is to be compared with a standard expenditure of 4.0-6.5 cents.

The largest item on the bureau budget was the salary of the bureau director. That was as it should be. The book bears unconscious testimony to the economy in paying for personal ability. For example, the active enlistment of literally hundreds in various projects was largely due to the resourcefulness and energy of the director.

Here, as in *A City Set On A Hill*, we note the lack of a program of health education, such as was discussed in the *Journal*, May and June, 1929, and, as was stated briefly in this department a month ago:

A program or a plan for health education, as we see it, is not the planning of the details of a particular project or event. Rather we are thinking of a plan or program for a year or other extended period. It is the selection of the objectives and the chief audiences and mediums mapped out in relation to the needs of the community and the resources of the health agency, or the group of health agencies.

There were programs, in the plural, the stressing of special themes, much planning. But there was too little time in Syracuse for the development of an underlying, inclusive program or the formulation of a philosophy of health education out of which such a program would have emerged. One might ask even if too much was undertaken, and

if the supervisory groups thought of health education largely as a succession of methods and materials to be manipulated with energy and varied skills.

Every public health worker concerned with the organization of health education will wish to read *Health Education in an American City*, by Louise Franklin Bache. Published for the Milbank Memorial Fund by Doubleday, Doran and Company, New York, N. Y. \$2.00. For sale by the A.P.H.A. Book Service.

Czechoslovak Republic Wishes to Hear from You—We hope that many readers will respond to this and other requests from outside of United States and Canada which we publish now and then. Please send samples of various types of health education and publicity.

We take very much interest in the field of public health education and would be glad if it is possible to send us some of the new issues on health education. The member of our staff, Mrs. Dr. Klimova-Fugnerova has been studying health education during the year 1932 and profited greatly by it. We try to do our best in this field even in these unfavorable conditions, and think the material of U.S.A. may be of great use to us.

From Dr. L. Votava, Chief of the Health Education Department, State Institute of Public Hygiene of the Czechoslovak Republic, Praha XII, Korunni Tr. 162.

"Propaganda in an Economy Programme"—Under this heading are reported addresses before the annual meeting of the National Baby Week Council. Several paragraphs seem to be equally significant in Canada, the United States, and elsewhere:

Reduced means are teaching us at least one valuable lesson—the lesson that expensive propaganda is not always the best propaganda. This should be a cheering reflection for many a committee whose depleted funds, so far from meeting a publicity bill, will scarcely cover running expenses.

. . . The critical financial situation was

itself a vital reason why health propaganda should not be relaxed. It was at present the duty of propagandists to safeguard from reduction the relatively insignificant amount at present devoted to public health work. This could be done by creating a strong public opinion on the necessity for health work.

. . . No forms of propaganda bore more immediate fruit than public health education. Speaking generally, the health services of this country were highly organized. The publicity problem of the day was to persuade the public to take full advantage of those services.

. . . It was perhaps not altogether unfortunate that, faced with the necessity of maintaining good publicity with very little money, we were forced to examine the old methods, to decide which had proved themselves effective, and which had become obsolete.

. . . I have found poster methods too expensive, but there are plenty of other methods of making the work known to the public. If you have a Baby Week, do it on a big scale, with a procession right through the town! If you are opening a clinic, treat it as an important event, and invite all the prominent people in the town to be present.—

Mother and Child, 5 Tavistock Square, London, W. C. 1. April, 1933. *9d*.

Health Education in Arizona—The State Board of Health has announced that

A Division of Health Education, state-wide in its scope, has been organized for the purpose of carrying out a comprehensive program of visual education in public and personal health matters. Coöperation of several agencies, including the U. S. Public Health Service, The Rockefeller Foundation, the University of Arizona, Extension Division, and the Metropolitan Life Insurance Company, has been secured for this state-wide program. The program is to be carried out by the use of motion pictures which will be exhibited in schools, before Parent and Teachers Associations, woman's clubs and other organizations or agencies interested in promotion of public health and welfare throughout the state.

The department has obtained complete motion picture equipment for this project, including projection machine and screen which may be used wherever electricity is available. Arrangements will be made to exhibit these motion pictures in any school in the state or before any organization interested in the subjects to which they pertain upon written request.

"In Conference"—"How Effective Is Health Education?" will be presented at the annual meeting of the National Tuberculosis Association, Cincinnati, May 16. Speakers: Mrs. Ruth Heavenridge, Indianapolis; Dr. John Sundwall, Ann Arbor; Mary P. Connolly, Detroit.

The Division on Educational Publicity, under the chairmanship of E. C. Lindeman, and Social Work Publicity Council will hold a number of sessions in connection with the annual meeting of National Conference of Social Work, Kansas City, May 20-26, 1934.

Dr. H. E. Kleinschmidt will conduct a publicity clinic at the biennial meeting of the National Organization for Public Health Nursing, Washington, April 25.

Mary Swain Routzahn led a round table on "Publicity and Annual Reports" at a regional conference of American Assn. of Hospital Social Workers.

Palestine Will Welcome Your Material—Reprints, copies of journals, and other printed material would be welcomed by editors of—

The health, medical and hygiene journals issued in Palestine.

The Jewish National and University Library has a large medical department and is also interested in receiving health, hygiene, and medical periodicals. This department is of great service to the physicians and medical scientists of the country.

Kindly address to K. L. Meltzer, Hebrew University, P.O.B. 340, Jerusalem, Palestine.

We hope that this and similar requests will be answered from the many countries represented among our readers.

Information Wanted—What have you or what would you suggest?

. . . any material on Health Education. I am interested in health programs in general,

but particularly in health measures, programs, outlines, etc., in the outpatient departments—which may include various clinics.—Edna Mae Barrios, R.N., Vanderbilt University, Nashville, Tenn.

. . . samples of literature suitable for me to use in my work as dental hygienist in a public school.—Ruth Neighly, H. W. Gillett Dental Clinic, Glen Cove, N. Y.

Hygeia for March, 1934—*Hygeia*, American Medical Assn., 525 No. Dearborn St., Chicago, Ill. (25 cents), contains:

Plumbing and health (based on Chicago outbreak); Facts and fallacies of cosmetic surgery; Does your nose know? Full speed ahead kills (modern rush); The child who stutters; What shall a man believe? (advertising); Cancer—its status today; Massage; Keeping the underweight child in school; Committee acceptance of whole wheat flours; Building for posture; Cold feet; Sex in middle and advanced life; Helping baby to grow up; Training for golf and competitive swimming; Modern voodooism; What happens when you move; "School and Health," with organizing for good team work, how home and school can work together, new health books for teachers and pupils; New books on health; Questions and answers.

"Yellow Jack" in New York City—The heroic tale of the struggle of man versus "yellow jack" is told dramatically in a moving and significant play by Sidney Howard. It is based on a chapter of Paul de Kruif's *Microbe Hunters*, and is now being shown at the Martin Beck Theatre, in New York.

Yellow fever epidemics have inspired other writers before. The story of "The Flying Dutchman," the subject of an opera by Wagner, tells of a ship stricken with this scourge. A description of an outbreak of yellow fever among the crew of a ship is also given in Coleridge's *Ancient Mariner*. But all this was before Walter Reed and his coworkers, Drs. Carroll, Lazier, and Agramonte, as a result of their investigations carried on in Cuba in 1900–1902, proved that yellow fever is transmitted by the bite of infected

mosquitoes, and in no other way; and long before the second chapter of yellow fever began in 1927 with the discovery by Stokes and his coworkers that Asiatic monkeys were susceptible to yellow fever and might be used as experimental animals; and even longer before the recent discovery of a special vaccine.

Sidney Howard begins his play at the end, presumably with the idea in mind that the modern knowledge of the cause of yellow fever will give new meaning to this dramatic triumph of man over yellow jack. But his intermissionless play deals mainly with Reed and those other brave men who volunteered to face the dreaded experiment of being bitten by infected mosquitoes.

It is worth seeing, this play on the conquest of science and the willingness of men to give their lives to the dreaded yellow jack, in the cause of humanity. It is a play of great importance, especially for social and public health workers (notwithstanding that at least one of Howard's buck privates volunteering for the experiment verges on caricature). You would not want to miss it.—Savel Zimand.

Dates Ahead—Through the year national and local events offer opportunities for the department, the association or the council to take the lead, to participate, or to be recognized. Doubtless some overlapping of dates and of interests will be settled in individual communities.

"Negro Health Week" is about over as this issue of the *Journal* appears.

April—"Early Diagnosis Campaign—Health Recovery Campaign" sponsored by tuberculosis associations.

April 28–May 5—"Youth Week" (formerly "Boys' Week"). Address: National Youth Week Committee, 211 W. Wacker Drive, Chicago, Ill. Tuesday, May 1, is "Health Day."

May 1—"May Day" or "Child Health Day." Address: American Child Health Assn., 50 West 50th St., New York, N. Y.

May 13—"Mothers' Day." Address: Maternity Center Assn., 1 East 57th St., New York, N. Y.

May 7—"Jubilee of Organized Camping." Address: Community Chests and Councils, Graybar Bldg., New York, N. Y. An opportunity for local groups to stress the values of organized camping.

"The Dominion is Preparing for Celebration of Several Important Anniversaries" reads a headline over a mention of commemorations of 100 to 400 year old events. We hope to hear that Canadian health workers are planning to show health progress and changes in health conditions in connection with the celebrations.

Early Diagnosis in 1934 — The February *Journal* had several pages about this campaign, sponsored by tuberculosis associations, and offering a significant opportunity for all types of health agencies to participate in making a real impression upon the community.

A usable range of printed matter, other help and plan suggestions have been prepared.

Get in touch with local, state or national tuberculosis associations.

"Mother's Day," May 13, 1934—This year "a planned economy of mother's lives" is proposed as the objective of Mother's Day celebrations. This is achieved by means of

. . . a country-wide effort to appraise the maternal facilities of each community. This is to be done by women's clubs, and men's clubs coöperating with local obstetricians, hospital executives, and medical societies. Local surveys are to be made using a blank appraisal form which the Association provides free. After such an appraisal, it will be seen more clearly just what is needed to effect improvement.

Every local club or group sending in a form will receive, without charge, a copy of the *Maternity Handbook*, by Anne A.

Stevens. The three clubs submitting the best appraisals will get a complete maternity display equipment, which may be used to teach maternity hygiene to mothers. The contest closes May 1, just in time so announcement of winners may be made by Mother's Day.

For men's clubs there is provided a suggested program for a meeting to be held the week just before Mother's Day. Publicity material in the form of ideas and suggestions for use with local newspapers and radio stations, will be sent to any local group on request.

Kiwanis International has sent to its 2,600 clubs a statement about Mother's Day. Rotary and Lions Internationals are expected to do likewise.

Address Maternity Center Assn., 1 East 57th St., New York, N. Y. for full information. A new 4-color poster, 14 x 22 inches, is sold at 10 cents.

Education and Prevention in New Jersey—Governor A. Harry Moore in his annual message to the 1934 Legislature:

The one important lesson in this field to be learned from the experiences of the last 4 years, it seems to me, is the necessity for some shifting of our emphasis in the attack upon this whole health and welfare problem. For many years past we have used the greater part of our energy and most of our expenditures in treatment and attempting to correct health and dependency conditions which ought never to have occurred, and we have given entirely too little attention to the preventive side of our public health work. Our institutional population has shown a steady and continued growth year after year, and, notwithstanding the extension of existing institutions and the construction of new ones, practically every state and county institution

for the custodial care of public wards is crowded to the doors and waiting lists continue to grow.

We must attack this problem at its source and this means the substitution of prevention to the greatest possible extent for care and cure. This also means a more determined attack upon disease, insanitation and unwholesome social conditions, more and better public health work, more and better clinics, more and better probation and parole work, more general health education, and, I trust, fewer persons in public institutions maintained at large annual cost when the greatest possible economy is practised. In the proportion that more funds are devoted wisely to preventive health work we may expect to save an increased amount at the custodial end.

RADIO

Next month we would like to pass over Illinois, Connecticut, and Baltimore, and give some glimpses of broadcasting by other state and local groups. We now receive mimeographed radio talks only from the three named above.

Baltimore Health Department:

Highlights in public health, temper tantrums, the lowly germ, rabbit fever, what is indigestion? check your health, eczema, keeping well in 1934, the longest war in history (tuberculosis), watch your weight, measles is here, baby teeth may need filling too, Mrs. Barclay learns about diphtheria prevention (dialogue).

Connecticut State Department of Health, Hartford:

New mental hazards, have you proof that you were born? the community X-rays its children, the public health nurse and tuberculosis program, odors and tastes in water.

Illinois State Department of Health, Springfield:

Diet and head colds in children, more about common colds, bone button infection in industry, the hide and hair industrial menace (anthrax), lead poisoning in industry and its prevention, phases of physical fitness in industry today, health heroes and public health, Dr. Banting and public health aids, Edward Jenner and vaccination, pure food laws and public health, what noise may do to public health, the challenge of pneumonia, anatomy and cell structure exhibits, one hundred years of Pasteur, economics of clean streams and sanitation, the woman who was ministering angel (Florence Nightingale), the story of inoculation, sewage treatment—an essential to

modern civilization, from sorcery to science, when healers were gods, one man's work in life saving (Dr. Park), accidental discovery in medicine and the part played by the layman.

Health plays are broadcast Mondays at 3:15 p.m., E.S.T., by New York State Dept. of Health over station WGY.

SOME TITLES

Do these suggest timely topics, or new slants on old material?

"Smallpox Visits You in the Person of Miss X"; "Upsetting Some Popular Beliefs Concerning Sleep"—Iowa State Dept. of Health, Des Moines.

"To Recent Arrivals" (to the newborn baby about registration); "Like a Forest Fire" ("catching" diseases)—Maryland State Dept. of Health, Baltimore.

HONORABLE MENTION

To Health Dept., Palo Alto, Calif.: for table of contents, an organization chart, an "Education and Publicity" section, and a diagram of city budget appropriations showing amount, percentage and per capita (health of course being the lowest).

MAGAZINE ARTICLES

"The Common Cold," by C. H. Gellenthien, M.D. *Kiwanis Magazine*, 520 N. Michigan Ave., Chicago, Ill. March, 1934. 15 cents.

"Disease Germs Often Swallowed With Our Meals" was a full-page, half pictures, half text, in *American Weekly*. Feb. 4, 1934. This is the Sunday magazine used by Hearst newspapers, the most widely circulated periodical in the United States. The article emphasized the message of the Committee for the Study and Promotion of the Sanitary Dispensing of Foods and Drinks.

"How Much Do You Weigh?" by L. I. Dublin. *American Magazine*, Springfield, Ohio. March, 1934. 25 cents. If over or under, "he tells what

bearing that answer has on your probable length of life."

NEW

Also new to us is *Arizona Public Health News*, State Board of Health, Phoenix. The Feb., 1934, issue was the 96th.

REPORTING

"Inventory for 1933," is a reporting of social hygiene work by state and local departments, associations and committees, and the United States governmental program for control of the venereal diseases, with a directory. 75 pages. *Journal of Social Hygiene*, 50 West 50th St., New York, N. Y. 35 cents.

Again the annual report of the health officer, Middletown, N. Y., "looks interesting." The 15 mimeographed pages are like no other mimeographed production we have seen. It is something to send for by the department or other health agency wishing to get its annual report read by a goodly proportion of the so-called "general public" and at a low cost. Here are two quotations:

It is difficult for people to understand why present methods of communicable disease control differ so widely from those in vogue short years ago. Does it seem strange to you that we do not close schools during outbreaks and that we placard fewer and fewer of these diseases?

We are not proud of our department's tuberculosis program for 1933. The control of tuberculosis is largely a nursing problem. It is obvious, however, that one nurse doing generalized public health in a city of 18,000 cannot devote the necessary time to it. With extra nursing service starting December 7, 1933, thanks to the C.W.A., we hope to do more intensive follow-up.

EDUCATION AND REFERENCE

"The Family Food Supply: What to Buy and Why." 23 pages. Metropolitan Life Insurance Co. Free.

"The Nature of Bacteria," by C. E.

Turner and Ellen L. Lytle. A suggested teaching plan based upon an experimental teaching project. 38 pages. Metropolitan Life Insurance Co. *Free*.

"Diets at Four Levels of Nutritive Content and Cost," by Stiebling and Ward. 59 pages. "Presents diets at four levels and includes information on certain aspects of food purchasing." Supt. of Documents, Washington, D. C. 5 cents. Probably *free* upon request to Bureau of Home Economics, Dept. of Agriculture, Washington, D. C.

"The Effect of Milk on Sleep" is a memorandum summarizing studies on this subject. National Dairy Council, Chicago. *Free*.

"The Psychology of Progressive Deafness," by G. Berry, M.D. Reprint from *Journal*, A.M.A. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. 12 pages. 10 cents; 10 copies, 50 cents; lower rates for more. Send a copy to the chief editorial writer of the newspaper having the most thoughtful editorial page.

"The Economic Aspects of Medical Care," is a revised list of reading references. Julius Rosenwald Fund, 4901 Ellis Ave., Chicago, Ill. *Free*.

"English Workmen Pay Their Hospital Bills," by M. M. Davis. Reprint from *Modern Hospital*. Julius Rosenwald Fund. *Free*.

"A Picture-Book About the Costs of Medical Care." 16 pages, largely picture diagrams. Julius Rosenwald Fund. *Free*.

Reprints from *Public Health Nursing*, 50 West 50th St., New York, N. Y. 10 cents each:

"Planning for 1934: Supervision." 2 pages.

"Treatments in School." 2 pages.

"The Rôle of the Public Health Nurse in Communicable Disease Control." 9 pages.

The following reprints from *Sight-Saving Review* are offered by Natl. So-

ciety for the Prevention of Blindness, 50 West 50th St., New York, N. Y.:

"Home Treatment of the Eyes," by W. L. Benedict, M.D., 5 pages. 10 cents.

"Routine Wassermann Test for All Expectant Mothers," by E. L. Keyes, M.D. 4 pages. 5 cents.

"The Eyes in Infancy and Childhood," by E. L. Coolidge, M.D. 3 pages. 5 cents.

"Why Wear Glasses," by P. A. Halper, M.D. 6 pages. 10 cents.

"Conserving the Sight of Myopic Children," by A. L. Brown, M.D. 4 pages. 5 cents.

"Eyesight in Mental and Physical Development," by A. R. Wilkinson, M.D. 7 pages. 10 cents.

"Contact Glasses," by W. S. Knighton, M.D. 6 pages. 10 cents.

A report of the Committee on the (proposed) American Museum of Hygiene appears in the A.P.H.A. *Year Book*, 1933-1934, page 54.

"Questionnaire Outline for Discussion Course on Welfare Resources." A study outline prepared by Assn. of Junior Leagues of America and distributed by Community Chests and Councils, Inc., 1810 Graybar Bldg., New York, N. Y. 19 pages. Questions as to conditions, possibilities, standards—all in their local application. "Health Problems," 4 pages, covers state and local boards of health, board of education, hospitals, clinics, dental clinics, public health nursing—but not other types of voluntary health work. *Free*.

"Publications and Memoranda," a new list of helps on publicity issued by Social Work Publicity Council, 130 East 22d St., New York, N. Y. Includes health education and helps for those doing health education.

The A.P.H.A. *Year Book*, 1933-1934, may well be studied for the declarations and various reports as desirable background material.

Well nigh indispensable is *Library Index*, edited by National Health Library of National Health Council, 50 West 50th St., New York, N. Y., at

\$2.50 for the weekly issues. Makes available much of the most useful of current periodical references touching nearly the whole range of public health topics.

THE INCOMING TRAY

The "Home of the North Carolina State Department of Health" is pictured on the cover page of *Health Bulletin* of the State Board of Health, with this caption:

Readers of *The Bulletin* are again invited to visit the offices of the State Board of Health at any time while in Raleigh. School teachers accompanying children to Raleigh should include the Health Department in their list of places to be visited.

Birmingham's Health, Jefferson County Board of Health, Birmingham, Ala., Feb., 1934, devotes most of its space with effective text and diagrams, to emphasizing this statement which appears on the cover:

Of all the cities in America, large and small, rich and poor, North and South, only two have destroyed their public health organizations as has Birmingham.

In "Public Health Education," D. V. Curry, M.D., describes his effective use, as medical officer of health, St. Catharines, Ont., of displays in empty stores. *Health Officers' World*, 2912 N. Hackett Ave., Milwaukee, Wis. 20 cents.

Illinois Health Messenger, Illinois State Dept. of Health, Springfield, appears for 1933 in a cloth bound volume with a rather full index.

The *Rochester Democrat and Chronicle* gave a good full-page to the Monroe County and Health Assn., Rochester, headed "Health Seals Spread Christmas Cheer." A variety of pictures occupied much of the page which, happily, cut down the amount of text.

The *New York Times*, Feb. 25, 1934, carried a 3-column wide picture of a

healthmobile used by Los Angeles. "Bringing Health to the Back Country . . . Covers the Remote Sections of the 1,094 Square Miles of the School District" . . . said the caption.

"Multigraphed and bound in the Milwaukee Health Department" was an attractive "Manual of Procedure and Guide for Coöperating Committees in Organizing Preschool Clinics." Excellent use has been made of the display type available for the multigraph; 6 by 9 inches; 16 leaves, plus stiff cover with a pleasing marbled finish; blank pages for "Notes" opposite every text page. If you have a multigraph you will wish to see this example of publication possibilities. 5 cents.

"Health and Baby Weeks in Ceylon," by J. H. DeSaram, in *Mother and Child*, 5 Tavistock Square, London, W.C.I. (Oct., 1933, 9d.), reports that

Health and Baby Weeks are now recognized both by medical officers of health and local authorities in Ceylon as effective means of educating the people in health matters.

The chief method adopted for interesting the public in this week at Dondra was by word of mouth through the schools and headmen, but the traditional method of the beating of the tom-tom and the distribution of posters and hand-bills was also employed. In connection with the clean-up day which preceded the demonstration, a special leaflet was issued. This drew the reader's attention to ten of the main health habits. A novel competition introduced at the Dondra exhibition consisted of a headman's test in elementary health knowledge.

We feel that someone should apologize for the amount of space in this department taken up by long, cumbersome titles of health agencies. And the newest of organizations has the longest and the most formidable of names! "There should be a law!" Really such names do handicap health organizations and limit their speaking and writing use.

BOOKS AND REPORTS

The Dynamics of Therapy in a Controlled Relationship — *By Jessie Taft. New York: Macmillan, 1933. 296 pp. Price, \$2.50.*

The therapeutic value for children resulting from the relationship between therapist and patient deserves the consideration of those interested in the behavior of children. This book gives the records of two such situations: (1) "An Experiment in a Therapeutically Limited Relationship with a Seven-Year-Old Girl," reprinted from the *Psychoanalytic Review*; (2) "Thirty-one Contacts With a Seven-Year-Old Boy as Preparation for Placement in a Foster Home."

In these accounts of the 16 and 31 hours spent, respectively, with these children over a period of weeks, the author gives in detail an accurate account picture of the relationship between herself and the patients. Her account of each child's reaction is not a description of what happened, but rather a verbal expression of the dynamics of the child's personality. The influence of the transference or analytic situation becomes apparent.

There is also a chapter on "The Time Element in Therapy," which is of value particularly to those who in clinic have to make the most of each hour with a patient. In the conclusion entitled "The Forces That Make for Therapy," are set forth some ideas regarding the reasons for life's failures and the sources and means of relationship therapy. The author adheres to many ideas given by Otto Rank.

The book has merit in weighing the possibilities of offering psychotherapy to individuals, either by social case work or by physicians. Dr. Taft does

not jump to any preconceived conclusions but honestly records what she noted. The book is well worth reading.

ELIZABETH I. ADAMSON

Food-Borne Infections and Intoxications—*By Fred Wilbur Tanner. Champaign, Ill.: Twin City Printing Co., 1933. 450 pp. Price, \$5.50.*

The author treats of a subject which has been much before the public for some years. He believes that the acceptance of ptomaines as causes of illnesses has retarded work along sound lines and calls attention to the fact that heat-stable gastrointestinal irritants formed by members of the staphylococcus and Salmonella groups furnish better explanations for food poisoning.

There is an introduction treating of the subject in general, followed by one on the hygiene of food, cooking, handling, etc. We are glad to note that he lays stress on the medical examination of food handlers. Insect carriers and other vectors are considered. The special types of infections are taken up under the heads of the groups of organisms which cause them. Extensive tables and accounts of a large number of reported outbreaks are given. The book contains a great amount of valuable material which will be useful for reference.

The printing and make-up are good.

MAZÛCK P. RAVENEL

Alcohol. Its Effects on Man—*By Haven Emerson, M.D. New York: Appleton-Century, 1934. 114 pp. Price, \$1.00.*

This is an excellent presentation, written for school teachers, high school and college students, of the subject em-

braced in the title. The book has been practically summarized in the 15 points enumerated in the preface concerning which there is agreement among those qualified to judge. The subject matter of the book is largely made up of matter going into more detail to prove the points mentioned. There is one inconsistency which may be mentioned. On page 105, the author quotes Sir Arthur Newsholme, well known as an extreme dry, as showing that 1 per cent of the adult males in England each year get drunk, in the official police sense, while 1 in 200 is legally convicted of public drunkenness. He goes on to say that crimes of physical violence with or without drunkenness are greater where the per capita alcohol consumption is high. The report of Baron Trenchard for 1932, just issued, shows that there were only 21 murders during that year in London, and up to approximately the middle of February, 1934, not a single murder has occurred.

The book is well written and contains many valuable facts. It ends by giving a list of 12 authoritative sources of information which have been consulted. Unfortunately, it has a jacket with the usual amount of blurb to which publishers seem addicted.

MAZÏCK P. RAVENEL

Diet and Personality—By L. Jean Bogert, Ph.D. New York: Macmillan, 1934. 223 pp. Price, \$2.00.

The title of this book will undoubtedly attract the attention of the "average man and woman" for whom it is admittedly written. The same average man and woman will find it easy, interesting reading, and concrete information may be obtained, but one seriously doubts the final effect upon personality.

An introduction by Dr. Mendel points out the "food conscious" attitude of the American public and recommends the fitting of diet to type.

The book is made up of 15 chapters

with the first 3 devoted respectively to the diet problem of the slender person, the stocky person and the person of medium build, which classification seems all inclusive. Then follow rather generalized discussions of such enemies to satisfactory living as nervous strain, city perils, lack of exercise, improper posture, indigestion, constipation, underweight. Good and bad health habits are listed and there are specific "Do's" and "Don'ts." Throughout these chapters, there are many references to the endocrine rôle in body types and the possibilities of diet in resulting conditions. A chapter on Reducing Diets suggests menus and foods suitable for the reducing-conscious reader.

The book is written in a popular, rather breezy style. It contains much informative material regarding general living conditions and health habits and diet.

It is printed on good paper in a type that will make it good reading for the general public.

ANNA DEAN DULANEY

Chronic Illness in New York City—By Mary C. Jarrett. Foreword by Dr. Ernst P. Boas. 1933. Published for the Welfare Council of New York City by the Columbia University Press. 2 vols.—Vol. 1, *Problems of Chronic Illness*, 258 pp.; Vol. 2, *The Care of the Chronic Sick by the Different Types of Voluntary Agencies*, 287 pp. Price for 2 volumes, \$5.00.

These two volumes represent, as Dr. Boas writes in the Foreword, "the first carefully considered review and interpretation of the many aspects of the problem of chronic disease, grounded on an adequate factual basis." The study describes critically the findings of a survey of the chronically ill and the facilities for their care in New York City; and suggests "a plan for an

orderly advance toward the prevention and care of chronic illness."

Miss Jarrett's work is a challenge to public health authorities. For, as Dr. Boas states, while the public health program has, during the last 50 years, gradually broadened its scope, "the social significance of chronic illnesses, which today are the chief causes of invalidity and death, have been largely ignored." This, notwithstanding the fact that for many years there has been an increasing demand for improvement of the chronic sick on the part of organized groups, physicians, nurses, and social workers. This study is best evidence of this demand. But so far only a beginning has been made in a few places.

To awaken the community to its responsibilities on this problem and to furnish accurate information in this field, the Research Committee of the Welfare Council of New York City has performed the very valuable service of carrying on a census of chronic illness in New York City, on which data Miss Jarrett based the report.

The census of the Welfare Council included all chronically ill persons under the care of medical and social agencies in New York City. Institutional agencies reported 56 per cent, and non-institutional agencies 44 per cent of the whole number. Nearly 21,000 cases were recorded, yielding a ratio of the dependent chronically ill, exclusive of those suffering from tuberculosis and mental diseases, to the general population of 1 in 310. It is estimated that this represents only one-third of the chronically ill in the entire city. In other words, approximately about 1 per cent of the population is disabled by chronic diseases.

The two most common misconceptions concerning chronic illness are, first, that it is always incurable; and second, that it affects chiefly the aged. Miss Jarrett's study points out that the

outlook for recovery from illness was favorable in one-fourth of the children and in one-tenth of the adults under 60 years of age. Regarding the second misconception, her study shows that nearly half of the chronically ill persons in the census were under 40 years of age; about one-third were under 16, chiefly children with orthopedic disorders, and nearly one-fourth of these children were under the age of 6; and only one-fifth of the whole number were over the age of 70. Moreover, the majority of patients were ambulant, only 30 per cent of the adults and 15 per cent of the children being confined to bed or to wheelchairs. Thus "chronic disease affects persons of all ages, and may occur at any time from the beginning to the end of life."

The control of mortality among infants and the prevention of deaths from tuberculosis, diphtheria, and other infectious diseases, have been and still are in the forefront of the public health program. But deaths from these diseases have been greatly reduced, and the major causes of present-day mortality center around the group of diseases affecting the heart, blood vessels and kidneys, cancer, pneumonias, and accidents. This shift is bringing about an increasing recognition of a change in the objectives of the public health program so that it be realigned to correspond with present conditions.

Miss Jarrett sets forth the essentials of a community program for dealing with chronic illness, and stresses the necessity for creating public recognition that prevention of chronic disease is the most pressing public health problem today. The rôle that departments of health should play in this new program, as well as the function of the voluntary agencies and how they can participate in the care of the chronic sick, are carefully examined by the author.

This study is an indispensable guide to those seeking accurate information

in the field of chronic diseases. It is only to be regretted that such excellent and authoritative source books should lack an index.

SAVEL ZIMAND

Heredity and Environment—By Gladys C. Schwesinger. New York: Macmillan, 1933. 484 pp. Price, \$4.00.

Heredity and Environment will either be considered an elementary revamping of three or four standard works, or a profound study "in the genesis of psychological characteristics," depending upon whether one is or is not familiar with the literature of psychological testing and personality measurement. Not that it is not a very useful book to one in either category—on the contrary, even the student of the field will find it a convenient summary of Pintner's *Intelligence Testing*, Symonds's *Diagnosing Personality and Character*, Hollingworth's *Vocational Psychology and Character Analysis*, and the *Twenty-seventh Year Book of the National Society for the Study of Education*, all brought up to date by the careful editing of last year's *Psychological Abstracts*.

It is an excellent textbook for courses in psychological measurement, for it is, in the main, an elaborate survey of the I.Q., its measurement, and the factors that influence it; but it is hardly, except in one portion, an adequate treatment of heredity and environment.

Why a study in genetics should devote almost two-thirds of its pages to listing measures of intelligence and personality and to summarizing superficially the viewpoints of the major schools of thought on what constitutes personality, and only about one-third (one of six chapters) to the subject of the book as indicated in the title, is difficult to see. It really consists of three distinct uncoordinated parts, and if each of these sections were published

separately, only praise for the author would be in order, for two of them would be compact summaries of (1) the field of intelligence and personality measurement, and (2) the variety of viewpoints on intelligence, while the third would be a monograph on recent studies of the effects of various environmental factors on the I.Q.

On the whole, the book is a very scholarly work, but it is unfortunate that three distinct unrelated studies were bound between two covers ostensibly as one study. Each portion serves a useful purpose, but only one serves the purpose of the book. Evidence of painstaking work abounds throughout, and specific references are so numerous that reading is sometimes made difficult; more than 800 references are included in bibliographies listed after each major chapter.

MORRIS KRUGMAN

Good Eyes for Life—By Olive Grace Henderson and Hugh Grant Rowell, M.D. New York: Appleton-Century, 1933. 202 pp. Price, \$2.00.

This volume is written in a sprightly style throughout; and its catchy phrases and the use of words in unusual meanings pique the curiosity of the reader. The names listed by the authors in their acknowledgments indicate that they had the coöperation of a number of leaders in the fields of ophthalmology and education. The quotations and the frequent references to the findings of scientific research suggest that they also have drawn upon the resources of an excellent scientific library. The well chosen collection of excerpts from scientific writings, even though presented in the Ripley, believe-it-or-not, style, leaves the reader with a sense of having been in touch with the truth.

It is in the interpretation of the facts that the reader is likely to find cause for objection. The presence of positive,

unqualified statements, as yet unsupported by authentic research, weakens the use by the authors of excerpts from scientific papers. Furthermore, flippancy, often in itself misleading, when used as a device to brighten up facts, is disappointing to one seeking information.

The authors are at their best in the material relating to the working or to the reading position for school children. It is regrettable that other sections of the book do not reach the same level, since there is genuine need for a popular presentation of scientific information on eye health. ANETTE M. PHELAN

The Chemistry of Flesh Foods and Their Losses on Cooking—By R. A. McCaense and H. L. Shipp. *Medical Research Council, Special Report Series, No. 187. London: His Majesty's Stationery Office, 1933.*

This work was undertaken largely owing to the lack of adequate knowledge of the chemical composition of foods, particularly meats, and because practically all existing analyses were on uncooked foods.

In three parts, there are given a description of the analytical methods employed, results obtained on a number of different kinds of fish, shellfish, meats and poultry, and the cause and extent of losses brought about by different methods of cooking.

The analytical methods are given in such detail that they may be duplicated. The cooking methods are scantily described and some would be hard to duplicate. The degree of "doneness" is one of the most important factors affecting cooking losses, and this can be accurately controlled only by the use of well made meat thermometers and thermocouples. The authors in many cases do not record the temperatures at which the meats were cooked, which is important in affecting the shrinkage. In view of the

fact that carcasses of the same animal vary one from another and that one cut varies from another of the same carcass, it would seem that accurate descriptions of the samples should accompany the analyses; also duplicate or paired cuts from the right and left sides of the same carcasses should be used, one analyzed raw, and the other after cooking.

The study is a valuable contribution to the knowledge of the composition of cooked meats and the effects of cooking. JESSIE A. CLINE

Nervous Breakdown—By W. Béran Wolfe, M.D. *New York: Farrar & Rinehart, 1933. 240 pp. Price, \$2.50.*

In the judgment of many, this economic depression from which we hope we are emerging is likely to result in—or has already resulted in—an excessive number of nervous breakdowns. Hence the timeliness of a good book dealing with this subject. A discussion of causes and symptoms; a series of case histories; a summing up talk with reader—these are the essence of the book under review.

Two or three short quotations will exemplify the theory on which the author proceeds. "The pattern of any individual's life is a pattern of compensation for the inferiority feeling experienced in childhood." "The strategy of an individual's life is directed toward a goal of security, superiority and well being." He then goes on to assert that failure to make progress toward this goal results in loss of "Face" on the part of the individual, and a nervous breakdown to conceal the true state of affairs. The cure comes about by acquiring a new sense of "Face" based on service to others. A number of actual cases are analyzed to show how this works out in practice. In the course of his discussion the author strays up a side path in a long

but interesting comment on the current economic depression as it affects the inhabitants of the United States. No epithets are spared in characterizing the attitude of the average American in the face of his lost sense of security.

This book, I imagine, may be more useful as a prophylactic than as a cure. The individual whose world has not yet slipped out from under him will find many hints on how to keep a firm footing. The author's style is vigorous and colorful. There seems to be no such word as fail in his vocabulary; his cases are all cures. This, I presume, is for the psychological effect on the depressed patient. The ideal of normality held up for guidance seems to be that of the "good mixer"; or perhaps Ebenezer Scrooge after the ghosts were through with him. The last chapter or two are not so good as the others, tending to dissipate the clearer impression of the body of the book.

All in all, an interesting treatment of a much misunderstood subject.

MERRILL E. CHAMPION

Great Men of Science—A History of Scientific Progress—By Philipp Lenard. Translated from the Second German Edition by Dr. H. Stafford Hatfield, with a Preface by E. N. da C. Andrade. New York: Macmillan, 1933. 389 pp. Price, \$3.00.

Although the names of the author of this book and of the writer of the introduction would seem to be sufficient guarantee of the authenticity of the work, the writer of this review has taken the precaution of submitting it to a well known physicist.

While not concerned with public health, it is believed that this book should be in the library of well educated scientific men, whatever their special interests may be. A number of the discoveries of those, sketches of whose lives are here given, have been adapted not only to medical practice,

but to some preventive measures, though none are directly concerned with public health. The articles concern not only those whose names are household words in all educated circles, but the author has rescued from a more or less deep oblivion the names of some who have not attained wide popularity, in spite of their contributions.

The translation seems to be excellent. The book is most readable and the illustrations, consisting almost entirely of photographs, would assure the value of the book, apart from its substance. The printing and make-up are all that could be desired, and the work can be unreservedly recommended.

MAZŮCK P. RAVENEL

Physiological Health—School of Education Series, New York University. Edited by Jay B. Nash, Chairman, Dept. of Physical Education. New York: Barnes, 1933. 308 pp. Price, \$2.00.

Physiological Health, the fourth book in a series of five to be published on Interpretations of Physical Education, is divided into 5 parts. Each part consists of a series of papers; effort being made to contribute to the subject from several pertinent viewpoints.

Treatment in a work of this size must necessarily be somewhat brief on many points, but a group of specialists was selected well qualified to discuss the particular topics assigned, all well known in the literature for their contributions along the lines involved in the present volume.

Cross references are given by a number of the specialists. The selected bibliography in health given as Part VII has been carefully compiled and is representative of the different activities which contribute to health.

The book does not have the continuity which would prevail in a book by a single author; on the other hand, it has the merit of presenting the views

of persons who have specialized in the fields which they discuss and in which they are respectively better known than a single writer would be.

This book is within the range of the average intelligent reader and deals with 6 main topics: Health Defined, The Forces and Factors in Building and Maintaining Health, Health as a Basic Potential, Health as a Basic Potential for Full Development, Teaching for Health, and Administration for Health.

C. E. TURNER

Safety in Physical Education in Secondary Schools—*By Frank S. Lloyd. National Bureau of Casualty and Surety Underwriters. New York, 1933. 167 pp. Price, \$1.25.*

This is a report on a study of the types and causes, with suggestions for prevention, of accidents occurring in the physical education program—including gymnasium work, sports, and athletics—in secondary schools.

The larger number of accidents in physical activities in the secondary schools—especially in football—has long been a cause of worry to physical educators and to school administrators.

This study, while showing a high accident rate for football, 8.75 per 1,000 exposures, shows that in proportion to the number participating the accident rate is higher in touch football, 17.11, and heavy apparatus work, 13.68; after football, the next highest rate is in lacrosse, 5.97, followed closely by wrestling, 5.71, and tumbling, 5.15.

Touch football—a supposedly innocuous sport—ranks first. Possibly this is due to the untrained condition of the players and to their lack of protective armor.

In number of days lost from classes—in proportion to number of exposures—heavy apparatus work is most hazardous, 88.0 days lost per 1,000; touch football, 81.52; wrestling, 72.44; and football 64.81.

An excellent summary of conclusions is presented and the report ends with recommendations as to means of accident prevention in this group.

This is an extremely valuable publication, particularly for those responsible for secondary school activities.

C. H. KEENE

The Teaching of Preventive Medicine in Europe—*By Carl Prausnitz. London: Oxford University Press, 1933. 180 pp. Price, \$3.75.*

This volume is made up of the Heath Clark Lectures, 1932, delivered at the London School of Hygiene and Tropical Medicine. It is based largely on personal observations by the author, supplemented by documents of the Health Section of the League of Nations. It is to be regretted that there are no reports from Belgium, Italy, the Netherlands, or the Scandinavian countries, all of which are doing very good work in the teaching of preventive medicine.

The book is a valuable contribution to our knowledge of the subject treated. Perhaps the most interesting chapter is the introduction of some 28 pages, in which are discussions of unemployment, malnutrition, etc., the only objection to which is that the data presented are not quite up-to-date. The author gives an excellent aphorism—"The greenhouse of civilization brings forth not only sweet fruits and beautiful flowers, but also poisonous weeds." He also brings forward an unanswerable argument in his statement that to advance preventive medicine is to the interest of the state, hence it is obvious that the state must do all in its power to stimulate and assist research by founding and maintaining adequate institutions of hygiene. As a fact, all enlightened countries now have such institutes which are being steadily improved and added to. There is a description of the teaching of preventive medicine in the various countries visited by the author,

with a fairly complete outline of what is being done, illustrated by some excellent photographs of buildings, laboratories, and lecture halls.

Practically all of these institutes are under state control and supported by the state, and the great majority of them were erected by aid from the Rockefeller Foundation. The volume ends with a chapter on the work of the League of Nations.

The value of the book would have been much increased for the average reader who has not been able to visit the countries and the institutes mentioned if the author had given a more extensive critical comparison of them.

The book is excellently printed and made up. MAZŸCK P. RAVENEL

Our Common Enemy: Colds—*By the Editors of "Fortune" in Consultation with Eminent Physicians. New York: McBride, 1934. Price, \$1.00.*

Every once in so often a layman breaks into print on a medical subject, and, as a rule, makes a mess of it. This time the editors of *Fortune* have tackled one of the least understood and

most difficult problems in medicine. The only conclusion that can be arrived at from their statements is, what all doctors have been aware of for a long time, that we know very little about the common cold.

The authors claim to have been in consultation with eminent physicians, whom they are very fond of speaking of as "No. 1," so and so. They have left out of consideration entirely perhaps the most monumental work on colds which has yet been published. As editors supposedly interested in good English, the authors should have avoided the use of "flu" for influenza. There is no such word to be found in either English or medical dictionaries.

The really useful part of this book is Part II, "The Cold Business," in which the various nostrums and quackeries are treated in a masterly manner, which ought to be a lesson to the public, though it will not.

The illustrations of germs which are found in colds, following page 47; are worse than useless. The book is well printed and is entertaining.

MAZŸCK P. RAVENEL

REPORTS

New Zealand—The report of the Director-General of Health of New Zealand for the year ended March 31, 1933, indicates progress in health activities as evidenced by declining death, infant mortality and morbidity rates. The 1932 death rate was 8.02 per 1,000 mean population, the lowest ever recorded in New Zealand. The birth rate was 17.09 and the infant mortality rate, 31.22 per 1,000 live births. With the exception of a minor epidemic of acute poliomyelitis (148 cases and 19 deaths), infectious diseases were generally marked by a distinct fall in incidence.

During the past 7 years individual records and histories of all persons treated for cancer in the public hospitals in the Dominion have been maintained by the Census and Statistics Office. There have been nearly 2,000 cases analyzed annually. These data have been published by the Government Statistician in the *Monthly Abstract of Statistics* during 1932. The method of keeping records has been standardized and brought into conformity in the four centers, and a follow-up system for cases which have left the hospital has also been developed.

Special attention has been given to

the question of malnutrition among school children. The conclusions drawn from an analysis of the 60,000 to 70,000 annual examinations over a 6-year period indicate that over the Dominion as a whole the nutrition of school children has been well maintained, although there is some evidence that a group of city children is showing clinical signs of malnutrition due to the economic depression. Measured by mortality and morbidity rates, the economic crisis has not yet shown any serious detrimental effect on the public health, nor has there been any increase in the proportion of in-patients treated in public hospitals.

Nashoba Health District, Mass.—The first annual report of the Nashoba associated boards of health gives a list of members of the board during the past year on the title page. The 14 towns comprising the District have been assisted by the Commonwealth Fund and the State Department of Public Health. Each town has 3 members on the board, which meets 4 times a year in the different towns in alphabetical rotation. The Executive Committee, composed of one member from each local board, meets monthly. The Health Unit is that group of trained personnel hired by and responsible to the Nashoba Associated Boards of Health. Additional services have been established in the control of communicable disease, nursing, laboratory, and sanitation. Records, reports, and vital statistics for the entire area are centralized in the Unit's office.

Professional advancement to physicians and nurses in the district through medical and nursing institutes and through fellowships for post-graduate study at recognized schools is another feature of the newly established program. The immediate effect of these new services developed by the Health Unit is evidenced in the increased rating

of public health activities in the District, as measured by the *Appraisal Form for Rural Health Work*, from 367 points in 1930 to 598 points in 1932, or an increase of 63 per cent.

Madison County Health Unit, Kentucky—The report of this Unit for the fiscal year ending July 1, 1932, indicates that tuberculosis is one of the outstanding causes of death in the county. Consequently a vigorous educational campaign and a systematic canvass of contacts of tuberculosis cases within a 3-year period were undertaken. Every person in the family of an active case was urged to have a physical examination, a tuberculin test, and, if indicated, an X-ray of the lungs.

Three venereal disease clinics were held weekly by the department, where 1,072 people were examined over 12 months, 55 per cent of the patients under supervision being colored. The work of the 19 midwives practising in the county (7 colored and 12 white) was supervised. More than 100 babies were delivered by midwives in 1931.

This is practically a descriptive account of the health department activities, without tabular statistical material, but attractively illustrated by a number of pictures. A noteworthy feature of this Health Unit program is the systematic organization of lay and professional committees.

Gibson County, Tenn.—Gibson County had an estimated population of 47,109 as of January 1, 1933, with 21 per cent of its people colored, and less than 1 per cent foreign born. The county, located in the western part of the state, is essentially agricultural and is said to be the second in the United States in the diversification of crops. There are 8 incorporated towns in the county, with a total population of about 12,000, no town having over 5,000 people according to the 1930 census.

The school enrollment in the 76 white and 31 colored schools is 10,000.

In 1930 the Commonwealth Fund subsidized the health department with the understanding that the county would gradually take over the entire cost of the work. In addition, the Fund has awarded study fellowships to physicians in the county.

Since 1930 the department has doubled its personnel. Approximately 50 per cent of the expectant mothers in the county have been under nursing care during the past 3 years. An attempt is made annually to examine all school children in the 1st, 3rd, 5th, and 7th grades.

The report of 23 pages is interspersed with interesting full-page photographs of various phases of health department activities.

Dayton, Ohio—A summary of health activities during 1933 appears in the January, 1934, bulletin of the health department, and indicates a birth rate of 15.2, a death rate of 11.7 per 1,000 population (9.9 corrected for residence), and an infant mortality rate of 48.8 per 1,000 live births. There were no deaths from typhoid fever or small-

pox. A 60 per cent increase was noted in deaths from tuberculosis "as a result of the depression."

The results of a survey made in 5 schools to determine the amount of undernourishment among relief cases showed that the children of many families not on relief are suffering more from straitened circumstances than are those who are. An anti-diphtheria campaign was undertaken with the result that approximately 1,000 children under 2 years of age have been immunized during the year. In 1933 there were 150 cases and 8 deaths from this disease, as compared with 176 cases and 16 deaths in 1932.

The hope is expressed that in the future the statement that "every physician's private office will become a health center" may be a reality; that immunizations against diphtheria, smallpox, and scarlet fever, as well as general physical examinations, treatment of a majority of the indigent sick, examination of children for school attendance, etc., may be conducted in the offices of private physicians. The city will assist in financing cases where the patient is unable to pay in full for treatment.

ABSTRACTS FROM RECENT FOREIGN SOURCES

CHILD WELFARE PROVISIONS OF THE SOCIAL WELFARE LAW OF 1933 IN DENMARK

Introductory statement—The social-welfare law of Denmark of 1933 is a codification of the social welfare and child welfare laws of that country. Several chapters of this law are devoted to child welfare. While previously the child welfare regulations were scattered in a number of laws and were administered by different bodies, the new law, superseding and amending the previous legislation, has consolidated practically all child welfare measures and has unified their administration.

Administration of the child welfare

provisions—In every commune, except Copenhagen, the child welfare work is to be performed by a social welfare committee (Social Udvalg) through a sub-committee on child welfare (Underudvalg) containing persons who are not necessarily members of the local government, but who must be well qualified for child welfare work. In Copenhagen there is to be a special child welfare board (Børnenaevn). This concentration of all child welfare work in one local body and the emphasis on qualifications rather than

on membership in the local government are innovations in the present law.

The child welfare work of all the communal social welfare committees is supervised by the National Board of Child Welfare (Landsnaevnet for Børneforsorg) consisting of 5 members, one of whom is the Chief Inspector of Child Welfare. The Board also passes final judgment on appeals against the decisions of the communal committees.

The Chief Inspector of Child Welfare, assisted by a number of inspectors, has general charge of child welfare work. Among other things he must inspect personally at least once a year the institutions for children; the inspectors must visit at least twice a year all the foster homes and institutions.

Extent of child welfare work under the new law—Under the new law the following branches of child welfare work will be conducted by the communal social welfare committees:

1. Supervision over children under 14 brought up outside of their own homes, all illegitimate children under 7, children under 18 residing with parents who receive aid from public funds

2. Preventive care of children residing with their parents or guardians, but lacking proper care or presenting problems of behavior

3. Supervision over children removed from their homes because they present problems of character or behavior or because they were mistreated by their parents or guardians

4. Care of juvenile delinquents who are not prosecuted or whose penalties have been remitted

5. Widows' and widowers' pensions

6. Public aid to children

7. Feeding of children in public schools

8. Maternity aid from public funds—

Lovtidende (official collection of laws of Denmark), Copenhagen, 1933, No. 28, and volumes for 1911, 1920, and 1928. *Socialt Tidsskrift*, Copenhagen, 1933, vol. 9, No. 4. Translator's comment.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Social Hygiene Marches On—How the various state and local health department venereal disease bureaus and non-official social hygiene associations survived or failed to survive the stormy days of the fourth year of hard times is recounted in bald detail. And the account is far from discouraging.

ANON. *Inventory for 1933. J. Social Hyg.* 20, 2:53 (Feb.), 1934.

Graded Milk Ordinance Enforcement—Cities which have enacted the standard (U.S.P.H.S.) milk ordinance and enforced it with sufficient thoroughness to achieve a rating of 90 per cent or better are listed. The purposes of the listing are to encourage cities in well doing and provide travelers with the names of places where they may drink milk without misgivings.

ANON. *Milk Sanitation Ratings of Cities. Pub. Health Rep.* 49, 4:111 (Jan. 26), 1934.

British Eugenic Sterilization Study—There is no ground for alarmist views of racial deterioration; no way to separate sharply dullness and mental defect; no scientific value in the Kallekak and Jukes chronicles; no evidence that sterilization of certified feeble-minded of previous generations would have affected incidence of mental defect in this; no evidence of excessive fertility in feeble-minded; no substitute for institutional care. On the other hand: two-thirds of all defectives are capable of community life; defectives make inefficient parents. The committee of the B.M.A. doubts the wisdom of compulsory sterilization, but if voluntary sterilization is to be enforced,

elaborate, and adequate safeguards are proposed.

ANON. Sterilization of Defectives. *Brit. M. J.* 3812:161 (Jan. 27), 1934.

Communicable Disease and the Nurse—"The modern health officer adapts his control measures to fit the epidemiological characteristics of each disease. . . . Just as the manner of the attack varies with the peculiarities of the several diseases, so will the rôle of the public health nurse be dependent upon those special characteristics of the disease which lend themselves to the nursing approach."

ANDERSON, G. W. The Rôle of the Public Health Nurse in Communicable Disease Control. *Pub. Health Nurs.* 26, 2:66 (Feb.), 1934.

Pasteurizing Canadian Milk—Almost everything that can be said about the pasteurization of milk will be found in this series of Canadian papers. The discussion, which is inclusive though not particularly new, covers milk-borne diseases, relative nutritional values, ordinances, supervision of pasteurization, and defects to be found in the plants.

BELL, W. J., *et al.* Safe Milk (etc.). *Canad. Pub. H. J.* 25, 1:1 (Jan.), 1934.

Business-like Epidemiology—How the Chicago Department of Health went about tracing down and showing up cases in the amebic dysentery outbreak (totaling 721 cases in 206 towns) is graphically recounted. A thorough and important committee report implicating cross connections is appended.

BUNDESEN, H. N., *et al.* The Outbreak of Amebiasis in Chicago During 1933. *J.A.M.A.* 102, 5:367 (Feb. 3), 1934.

Does the "Modern Pace" Kill?—If death rates in circulatory and renal conditions are studied as a whole, increases after the fifth decade are slight and have mounted little since 1910. Rates for infectious diseases have fallen

in every age group. If circulatory and infectious rates are added, the combined death rate tends to attain equilibrium. The theory that "stress and strain" accounts for present day cardiac death rates is not supported, for the rise in circulatory diseases depends on the fall in the infectious diseases, not in early life, as often assumed, but in the very decades in which circulatory increase occurs.

CORN, A. E., and LINGG, C. Heart Disease from the Point of View of the Public Health. *Am. Heart J.* 9, 3:283 (Feb.), 1934.

Children of Tuberculous Parents—Tuberculosis mortality, 15-39 years, was two or three times as high among the offspring of white tuberculous parents as in a control group. Removal of the ill parent or carelessness in the home seemed to be of little importance.

EVARTS, H. W., *et al.* Tuberculosis Among the Children of Tuberculous Parents. *Am. Rev. Tuberc.* 29, 2:123 (Feb.), 1934.

About Children's Sleeping Habits—Warm milk at bedtime induces quiet sleep in children; other beverages have no consistent effect. Large amounts of food at bedtime result in marked restlessness. Baths seem to have no constant effect. Children have definite sleep patterns; they are quieter in cold weather than in hot.

GOODINGS, G. Normal Sleep Pattern for Children. *J.A.M.A.* 102, 7:525 (Feb. 17), 1934.

Difficulties in Dealing With Amebic Dysentery—Some of the uncertainties about the late Chicago amebic dysentery cases are presented to round out the picture of the outbreak's epidemiology. Even as to hand washing by food handlers the question is raised: "It remains to be seen whether any considerable number of individuals can be made sufficiently conscious of the possible menace to others to render this measure effective."

McCox, G. W. Amebic Dysentery. Pub. Health Rep. 49, 5:141 (Feb. 2), 1934.

Preventing Congenital Syphilis—Antenatal treatment of pregnant syphilitic patients reduces fetal deaths and syphilitic infants strikingly; results are proportionate to treatments given; even a few treatments will materially alter the outcome.

McKELVEY, J. L., and TURNER, T. B. Syphilis and Pregnancy. J.A.M.A. 102, 7: 503 (Feb. 17), 1934.

Putting Taste-Appeal in the British Diet—"If we imagine that there is great need for economy in the family budget, we even suggest bloaters, full of body-building material, for dinner. No doubt they are, but how many people like bloaters. To the man in the street the bloater is a joke, not a food. . . . I have personally tried some of the cheap daily dietaries advocated for diminished family budgets. I did not enjoy the experiment."

MURRAY, J. O. The Public Health Outlook in Nutrition. Pub. Health. 47, 5:162 (Feb.), 1934.

Depression Health De-bunked—In three more cities the new-poor were found to be suffering from diseases greatly in excess of the rate of the still-independents, and of their own rates while they still "had it." "It can be said," concludes the paper, "that none of the beneficent effects often attributed to the economic depression are evidenced by the data. On the contrary, illness has not been most frequent among those who have had to 'tighten their belts' most."

PERROTT, G. St. J. and COLLINS, S. D. Sickness and the Depression. Milbank Quart. Bull. 12, 1:28 (Jan.), 1934.

Streptococci in Colds and Influenza—Streptococci and pneumococci isolated in studies of colds, in-

fluenza, and pneumonia have distinctive curves of cataphoretic velocity. Convalescent serum from colds and influenza cases slows the cataphoretic time of the respective streptococci and this (corresponding with the specific antibody action) indicates the close relationship of streptococci from colds and influenza and that they have etiologic significance.

ROSENOW, E. C. Cataphoretic Time and Velocity of Streptococci and Pneumococci. J. Infect. Dis. 54, 1:91 (Jan.-Feb.), 1934.

For Gassed Sewage Works Employees—Victims of carbon monoxide poisoning in sewers or sewage treatment plants, if suffocated, should be given prone pressure resuscitation, warmed, stimulated with coffee or hypos, given complete rest, and for 20 or 30 minutes given oxygen and carbon dioxide. Plants should be equipped with the appropriate apparatus.

SAYERS, R. R. Gas Hazards in Sewers and Sewage Treatment Plants. Pub. Health Rep. 49, 5:145 (Feb. 2), 1934.

Reducing the Tax of Tuberculosis—In this editorial, Professor Winslow develops a telling conception of health economics which other sanitarians might well put to other good uses; upon the subject of reduction of taxes, he recounts the lowering of the tax of tuberculosis on humanity. Similar pictures might be drawn of the tax of typhoid, the tax of diphtheria, etc.

WINSLOW, C.-E. A. One Way to Reduce Taxes. Pub. Health Nurs. 26, 3:119 (Mar.), 1934.

More Typhoid Carriers—How each epidemic of typhoid fever creates a new crop of carriers and establishes the possibilities of food-borne infections is brought home to the water works operator.

WOLPERT, N. W. The Typhoid Carrier Problem. Water Works Engineering. 87, 4:160 (Feb. 21), 1934.

NEWS FROM THE FIELD

TRAINING COURSE FOR HEALTH OFFICERS

THE University of California, in its Intersession and Summer Session of 1934, will offer 12 weeks of intensive training for health officers. The session opens May 14 and closes August 3. The course is open to any person with the degree of doctor of medicine, but because of the nature of the work the class will be limited in number.

The first 6 weeks of the course will be conducted in Berkeley, Calif., under the general direction of Dr. Frank L. Kelly, F.A.P.H.A., and will consist of class instruction, group discussions, and field demonstrations. The next 4 weeks will be spent in the San Joaquin County Health Unit. During this period each student will receive practical field experience under the supervision of Dr. John J. Sippy, F.A.P.H.A. In the last 2 weeks each student will be required to make a survey of the health work in a community near to Berkeley.

The regular fees of the Intersession and Summer Session of \$35.00 for each session will be charged. There will be no laboratory fees.

Applications for admission should be

sent to Dr. John N. Force, Chairman, Department of Hygiene, University of California, Berkeley, Calif., and should be accompanied by a statement of professional training and experience. Those wishing to attend should make application as early as possible.

DR. CAMPBELL GIVES SALMON
MEMORIAL LECTURES

THE 1934 series of Salmon Memorial Lectures will be delivered by Dr. Charles Macfie Campbell, Professor of Psychiatry at Harvard Medical School, Harvard University, and Medical Director of the Boston Psychopathic Hospital. The subjects are announced as follows: Lecture 1, "Trends in Psychiatry," Lecture 2, "Classification vs. Dynamic Analysis," Lecture 3, "Conclusions and Suggestions." The lectures will be given at the New York Academy of Medicine, 2 East 103 Street, New York, on April 13, 20, and 27.

MARYLAND COUNTY HEALTH SERVICE

DR. R. H. RILEY, Director of the Maryland State Department of Health, advises that Caroline County,

Md., has now provided full-time county health service, giving the state a 100 per cent county health service.

Allegany County went on a full-time basis in 1922, and has the honor of being the first to organize such service. With the full coöperation of the county authorities, one after another of the 23 counties has been added to the list. The development by counties has been as follows:

1922—Allegany; 1923—Montgomery; 1924—Frederick, Baltimore, Calvert, and Carroll; 1927—Prince George's, and Talbot; 1928—Harford; 1929—Cecil, and Wicomico; 1930—Kent, Washington, and Anne Arundel; 1931—Garrett, Dorchester, Queen Anne's, and Worcester; 1932—St. Mary's, Charles, Somerset and Howard; 1934—Caroline.

In addition to being responsible for the health service of Anne Arundel County, the unit for that county is used as a training center and furnishes opportunities for field work for students in public health administration.

COMMITTEE ON CHILD WELFARE LEGISLATION

A COMMITTEE to study child welfare laws and to draft a bill on child welfare was recently appointed by the President of Uruguay. The committee consists of 8 members. Most of them are physicians who have been active for many years in child welfare work.—*Diario Oficial*, Montevideo, 1933. No. 8014.

LILLIAN D. WALD'S BIRTHDAY

ON the 10th of March Miss Lillian D. Wald celebrated her 67th birthday, and a group of children from the lower East Side of New York City broadcast their songs to her in Westport, Conn., from radio station WEVD.

Until she moved to the country for her health a year ago, Miss Wald had spent forty years as a neighbor of these children, their parents, and their grandparents on Henry Street. She founded

the Henry Street Settlement in 1893. The children sang under the direction of Mrs. Hedi Katz, head of the Music School of Henry Street Settlement. An interesting gift for Miss Wald was a specially bound volume containing Italian, Russian, and Jewish folk songs of New York's East Side, gathered and written for the first time under the supervision of Mrs. Martha Ramsey.

NURSES' 1934 BIENNIAL CONVENTION WASHINGTON, D. C., APRIL 22-27

THE American Nurses' Association, the National League of Nursing Education, and the National Organization of Public Health Nursing, will all have separate sessions as well as joint meetings of all three.

The *A. N. A. Bulletin* for March, 1934, gives the tentative programs of the A.N.A. and the N.L.N.E., and *Public Health Nursing* for April gives the program of the N.O.P.H.N.

These are the hotels to be occupied as headquarters during the Biennial Convention:

MAYFLOWER—American Nurses' Association.

WILLARD—National League of Nursing Education.

WASHINGTON—National Organization for Public Health Nursing.

WARDMAN PARK—Student Nurses.

POWHATAN—Exhibitors.

For further information, write to the American Nurses' Association, 50 W. 50th Street, New York.

OCCUPATIONAL DISEASE CLINIC

NEW YORK University and Bellevue Hospital Medical College recently opened a special clinic for occupational diseases, with a laboratory equipped for the work. Cases of lead poisoning, silicosis, occupational dermatoses, and benzene poisoning are among the cases being handled in the clinic, which meets Wednesday afternoons. Physicians and industrial health workers have been invited to refer cases.

WASHINGTON STATE HOLDS PUBLIC HEALTH INSTITUTE

A PUBLIC health institute is to be held under the auspices of the Washington State Department of Public Health at the State College of Washington, Pullman, Wash., on May 4-5. It is expected that a permanent organization of public health workers will be effected, possibly to be known as the Washington State Public Health Association.

CAN YOU PROVE IT?

BACHELORS and maids, fathers and mothers, alike received a little blue slip distributed for New Mexico's Bureau of Public Health by the State Comptroller's office with license plates for automobiles. Thus the reaching of a considerable proportion of the state's population was secured at the cost of printing some 60,000 small slips. Our correspondent reports:

As you may imagine, Miss Tober, state registrar, has had some quite amusing replies from the bachelors of the state.

Here is the copy (8 pp.):

Attention, Fathers and Mothers! Your automobile is now legally registered. You can prove its age and ownership. Can you do the same in regard to your baby?

If you are not certain that your baby's birth is registered write to the State Registrar, Bureau of Public Health, Box 711, Santa Fe, New Mexico, for this information.

PERSONALS

DR. HOWARD MORROW, of San Francisco, Calif., member A.P.H.A., has been appointed President of the California State Board of Health, succeeding Dr. John H. Graves.

DR. BERNARD W. CAREY, of Detroit, Mich., F.A.P.H.A., medical director of the Children's Fund of Michigan, was elected President of the Michigan Public Health Association at its last annual meeting, succeeding Dr. William J. V. Deacon, of the State Department of Health, also Fellow A.P.H.A.

CONFERENCES

April 16-17, Eighth Annual Meeting of the Florida Section of the American Water Works Association, Daytona Beach, Fla.

April 16-20, Eighteenth Annual Clinical Session of the American College of Physicians, Chicago, Ill.

April 22-27, Nurses' 1934 Biennial Convention. American Nurses' Association, National Organization for Public Health Nursing, and National League of Nursing Education. Washington, D. C.

April 26, A Hearing on the Problems of Cancer, under the auspices of the New York City Cancer Committee, New York, N. Y.

May 1-6, National Conference on Fundamental Problems in Negro Education, Washington, D. C.

May 14-17, 30th Annual Meeting of the National Tuberculosis Association, Cincinnati, Ohio.

May 15-20, Meeting of Royal Sanitary Institute, Norwich, England.

May 26-29, Annual Meeting of American Association on Mental Deficiency, New York, N. Y.

June 4-8, Annual Convention of the American Water Works Association, Hotel Commodore, New York, N. Y.

June 11-13, Twenty-third Annual Meeting of the Canadian Public Health Association, Montreal, Que., Canada.

June 25-27, Annual Conference of Health Officers and Public Health Nurses, together with American Association of School Physicians, Saratoga Springs, N. Y.

June 25-30, Annual Meeting of the American Home Economics Association, New York, N. Y.

July 9-14, Health Congress, to be held under auspices of the Royal Sanitary Institute, Bristol, England.

August 6-10, Annual Meeting of the American Dental Association, St. Paul, Minn.

Number 5

Exposure as a Factor in the Age Distribution of Measles, Diphtheria, and Poliomyelitis^{*†}

W. LLOYD AYCOCK, M.D.

*Assistant Professor of Preventive Medicine and Hygiene, Harvard Medical
School, Boston, Mass.*

IN the last analysis the distribution of infectious disease is primarily a function of exposure to, and infection ‡ with, the causative agent although it may be secondarily markedly modified by other factors such as immunity from previous exposure, some other quality of resistance on the part of the host, or by variation in the dosage or virulence of the infective agent. For example, it may be stated with a very considerable degree of certainty that certain "diseases of childhood" have come to be designated as such, first, because opportunity for infection is likely to come relatively early in life, and second, because with advancing age an increasing increment of the population is immune to the disease as a result of this earlier exposure.

However, as is well known, the diminution in the frequency with which certain of these diseases occur with increase in age in seeded populations cannot be wholly accounted for by increase in serologic immunity with age. In certain diseases the chances of infection have seemed so general that this discrepancy has been ascribed by some epidemiologists to a nonspecific resistance which is a function of increase in age itself, equal chances of infection at all ages being assumed.

In the case of certain helminths and protozoa young animals are naturally or may be experimentally infected, while it is difficult or in some cases impossible to infect older animals in which immunity from previous exposure can be ruled out. This indicates a greater resistance on the part of the older.

On the other hand, Smillie and Augustine,¹ and Augustine, Helmy and Nazmi² have shown that the occurrence of ancylostomiasis and ascariasis in man at different ages varies directly with insanitary habits making for exposure and permitting infection. The data presented in this paper, it is be-

^{*} Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

[†] This work was supported by the Harvard Infantile Paralysis Commission.

[‡] For the sake of clarity the term "infection" in this paper is used to describe actual contamination or infestation with the infectious agent in question while the term "exposure" is used to designate proximity to a source of infection, usually residence in the same household with a case, but not necessarily actual harborage of the infectious agent.

CHART I

lieved, tend to show that variations in the occurrence of measles, diphtheria and poliomyelitis at different ages, over and above that which may be ascribed to "immunity from previous exposure," are due in part to variation in the frequency of exposure at different ages, and in part to variation in frequency of infection in the exposed. Observations by Pope³ showing a difference in the incidence of scarlet fever in exposed males and females indicate that the variation in the frequency of this disease as between males and females under the same apparent conditions of exposure corresponds with obvious differences in personal, social, or what might be called household habits, of the two sexes at different ages, which habits in themselves constitute the necessary conditions for infection.

The data employed in making the computations on measles are those published by Chapin⁴ relating to 14,376 cases, 1917-1923 in Providence, comprising the number of persons exposed (living in the family with a case), the

number of immunes (giving a history of a previous attack) and cases, all by single year age groups up to 20 years, and the totals for adults. After making an additional adjustment for estimated transient maternal immunity in infants and using three-way moving averages to facilitate comparison, Chapin's data are plotted in Chart I. The essential point brought out by Chapin in the present connection is that there is considerable variation dependent on age in the frequency with which non-immunes in families with a case of measles contract the disease. After giving due consideration to the question of forgotten attacks, about 90 per cent of non-immune children, and less than 20 per cent of non-immune adults contracted the disease. From collateral knowledge of measles there are reasons for believing that an enumeration of cases would actually represent infected exposed non-immunes. Thus from the difference between the age curve of exposed non-immunes and that of cases an age curve of infection in exposed non-immunes can be figured.

CHART II

Polio-myelitis

CHART III

The data used in diphtheria are taken from the annual reports of the Superintendent of Health of Providence (Chapin)⁵ 1889–1901, comprising tabulations similar to those for measles. Chapin's data on diphtheria are similarly plotted in Chart II, calculating the non-immunes from average Schick results,⁶ and the infected exposed non-immunes by using an age curve of infection obtained by actual culture on other members of the family with a case. Such a computation, when compared with the age curve for cases, indicates that at all ages cases of diphtheria closely parallel infected exposed non-immunes. In other words, actual infection in non-immunes produces diphtheria with approximately equal frequency at all ages. However, this does not mean that all infected non-immunes develop the disease, but only that risk of disease in infected non-immunes appears to be equal at all ages.

The data on poliomyelitis (Chart III) are those collected in the course of field investigations of 1,573 cases of the disease in Massachusetts, 1927–1931, with similar tabulation of cases and all members of the families in which the cases occurred, by age. The number presumably immune, by reason of a previous attack, was of course negligible. The computation of non-immunes is on the basis of results obtained with the neutralization test on the general population of Massachusetts⁷—on a small scale to be sure—but giving figures closely corresponding to immunity to diphtheria as shown by the Schick test. For calculation of the infected exposed non-immunes in poliomyelitis, the diphtheria age curve of infection is used. Whatever justification for this there may be lies in the belief that the close correspondence between the rate of development of immunity to diphtheria and of poliomyelitis from the point of view of age is indicative of similar laws of infection in the two diseases. It will be noted that, as in diphtheria, the calculated age curve of infected non-immunes fairly closely parallels the age curve of cases.

In Chart IV are shown the age curves of infection as indicated by Chapin's data on measles and as determined by cultures on members of families with

CHART IV

cases of diphtheria. These curves are adjusted for comparison of age only. Studies by Kusama and Doull⁸ on carrier infection among family associates of diphtheria patients and carrier studies in school children by Doull and Fales⁹ are in general agreement with Chapin's findings in diphtheria, in so far as variation in the frequency of carriage with age is concerned.

Perhaps the point may be made clearer by expression of the results in terms of attack rates at different ages. In charts V, VI, and VII are shown the age distribution of cases of the three diseases together with attack rates in the total population, in the exposed population, in the exposed non-immune population, and, finally, in the calculated infected exposed non-immune population. All the curves are adjusted to bring them into comfortable position without distortion for comparison so far as age is concerned, and hence are to be taken as representing variation with age only and not as actual rates.

It suffices to point out that in measles

the comparative attack rates in infected exposed non-immunes for different age groups, from the nature of the data, plot as a straight line; those of diphtheria and poliomyelitis, although irregular, likewise suggest an attack rate in infected exposed non-immune individuals approximately equal at all ages.

CONCLUSIONS

The variation in the occurrence of measles, diphtheria, and poliomyelitis in non-immune persons at different ages would appear to be due in part to a difference in the frequency with which persons of different ages are exposed to respective viruses, and in part to a difference in the frequency with which persons of different ages are infected under the same apparent degree of exposure.

The differences in the risk of infection at different ages in measles, diphtheria, and poliomyelitis would appear to be due to quantitative or qualitative differences in personal, social or house-

hold habits of persons of different ages, which habits constitute sanitary habits in the present connection.

However, there is nothing in this which would detract from the view, previously expressed,¹⁰ that whether disease is to be the result of infection in a non-immune individual—at least so far as poliomyelitis is concerned—is determined by autarceologic factors. In

fact, since this study indicates that variation in these diseases with age can be accounted for wholly by exposure, infection, and immunity, it implies that autarcesis, although varying with climate and possibly with season,¹⁰ does not vary with age.

This study suggests further investigation of household habits at different ages looking to a clearer definition of the degree of exposure necessary for infection and possible improved sanitary measures against the spread of "contact" infections.

Faddism

. . . Finally, we should avoid faddism and easy ways to attain an hypothetical goal, scrutinizing with care the elaborate claims of manufacturers of this, that, or the other concentrated, desiccated and biologically assayed preparation.

Man cannot live by bread alone, but neither can he substitute for the natural fruits of the earth the dynamic contents of a pill of any potency.—Joseph Garland, M.D., *Dental Health, New Eng. J. Med.*, Mar. 15, 1934, p. 570.

The Isolation Time of Scarlet Fever*

J. E. GORDON, PH.D., M.D., AND G. F. BADGER

*Division of Epidemiology, Herman Kiefer Hospital, Department of Health,
Detroit, Mich.*

A REVIEW of American administrative practice¹ demonstrated an isolation period of about 4 weeks as the accepted standard for scarlet fever. Twelve among 44 of the largest cities of the United States required restriction of the patient for at least 28 days, and in 20 cities the period was 30 days. The minimum isolation varied from 21 days in 9 cities, to 42 days in 2.

Successful isolation of a specific communicable disease demands satisfactory protection of both immediate and remote contacts with minimal restriction of the patient. Control measures should, furthermore, be adjusted to the current behavior of the disease. Because of the present mildness of scarlet fever, restrictions may well be decreased. At the time isolation regulations were formulated, scarlet fever was a far more serious condition. In the event that the disease should show a tendency to return to its former severity, regulations should be revised promptly.

Present-day practice in the isolation of scarlet fever is based on empiric opinion, with general rules for all patients, irrespective of severity of the disease or the probable degree of communicability. Lack of information requires this type of administrative practice. It contrasts sharply with the

efficient and individualized regulations for patients with diphtheria or typhoid fever.

Observations in Detroit,² showed that after 4 weeks of uncomplicated scarlet fever, no more satisfactory control was accomplished by requiring absence of hemolytic streptococci in cultures from the nose and throat before patients were released. The measure of efficiency was the infecting case rate, namely, the percentage of patients known to be responsible for familial scarlatinal infections within 30 days after release. The infecting case rate was reduced somewhat by requiring negative cultures before dismissing patients with suppurative complications.

Because of the deficiencies in bacteriological control, studies were directed toward determining differences in the clinical and epidemiological nature of the disease which could be applied practically in the individualization of control measures.

The incidence of secondary cases was found to vary with the age of the original patient, the presence or absence of complications, and the season of the year. Information collected during several years indicated that, after release, children were far more likely to transmit infection than were older persons. For children under 5 years of age the infecting case rate was 5.5 per cent, 11 times that for patients older than 14 years. Every age group had an infecting case rate during the summer which was less than that of the winter and spring.

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

These studies were aided by grants from the Rockefeller Foundation, the Commonwealth Fund of New York, and the Committee on Administrative Practice of the American Public Health Association.

This information suggested the reasonableness of varying the isolation time with the season of the year and distinctly shortening the restriction for older persons. These theoretical considerations have been tried for 4 years under field conditions.

Since 1929 the isolation requirements for patients with uncomplicated scarlet fever have been reduced gradually (Table I). During the winter and

shortened to 3 weeks. Those less than that age were restricted for the usual 4 weeks throughout the year. Throughout the next year, 1931, the older group was isolated for only 3 weeks, except that in November the division between older and younger persons was changed to 15 years instead of 20. Children were isolated for 4 weeks during the months of January through June, and for 3 weeks from July 1 to November 10. The revision of 1932 established the isolation period for patients over 15 years at 3 weeks for the first 6 months and only 2 weeks for the summer and fall. The isolation time for children remained the same as in 1931, except that the 3 weeks' isolation period extended throughout December, instead of ending November 9. No changes were made in 1933. In 1934, the regulations which have recently applied only to the summer and autumn months, will be extended throughout the year, so that for the whole of 1934 older persons will be isolated for 2 weeks and children for 3 weeks, providing the infection is uncomplicated. The younger group will, however, be restricted to the premises for an additional week of observation.

TABLE I
MINIMUM ISOLATION TIME FOR UNCOMPLICATED
SCARLET FEVER—DETROIT

Time	Isolated 4 weeks	Isolated 3 weeks	Isolated 2 weeks

Totals						569	77.3						405	62.7	

These figures represent a sample of 974 from a total of 2,356 cases isolated at home. Cases reported after the first week of illness where the date of onset could be determined definitely were given credit for this time. Therefore, the actual isolation was less than the prescribed minimum.

worth of these shortened isolation periods. This was the last year in which a minimum 4 weeks' isolation was maintained for all patients. The infecting case rate in 1929 was 3.8 per cent and represents the average experience in Detroit. The rate for adults over 15 years of age was 0.5 per cent; that for children, 5.0 per cent (Table II).

The infecting case rate in the years that followed did not exceed that of the control years although the isolation time was progressively shortened. The

1931 rate was materially better. The relative frequency of infecting cases among adults and children was not disturbed, despite the fact that during 2 of the years, 1932 and 1933, the isolation period for adults was decreased by a half. The reduction in days of disability has been material (Table III).

SEASONAL VARIATIONS IN INFECTIVITY OF SCARLET FEVER

A seasonal variation in the communicability of scarlet fever has been

TABLE IV
CASES, INFECTING CASES, AND INFECTING CASE RATES BY SEASON AND YEAR

demonstrated for patients isolated 4 weeks.² This was attributed in large part to the greater frequency of complications during the winter and spring months. However, there is a seasonal difference in the frequency of secondary cases after simple, uncomplicated scarlet fever. These observations indicated that a variation in the length of isolation dependent upon season might also be practicable. This was first tried in 1930 (Table I).

Despite decreased isolation periods, the gross infecting case rate has not increased during any of the 4 years. The relatively greater rates during winter compared with summer months has been maintained each year. The average rate for the summers is slightly less than the rate for the summer of the control year, but not significantly. The 4 year program materially decreased the period of restriction with no apparent spread of infection (Table IV).

CONVALESCENCE OF ADULT PATIENTS RELEASED AFTER 14 DAYS

A public health program for preventing the spread of a communicable disease should be distinguished from its medical management. The time limits are not necessarily the same. With a disease such as typhoid fever, public health care may be essential well beyond the time when the patient has recovered clinically. By contrast the complications of scarlet fever and measles may require medical observation much longer than demanded by any danger of communicability. If the need for medical care exceeds the limits of communicability, restriction to an indoor life may well be terminated in the interests of a more favorable convalescence. Furthermore, the loss of school time for child contacts and the loss of employment for those of adult age is reduced. Realizing the distinction and yet the equal importance

of public health care and medical care, the results have been determined from both viewpoints, when adult patients were released after a period as short as 2 weeks.

It is a matter of common observation that complications of scarlet fever develop most frequently during the 3rd week of the disease, the so-called second or allergic disease period. However, the common suppurative complications are largely limited to children. During the past 2 years 139 adult patients have been released after 14 days' isolation. Essentially one-half were isolated in the hospital and one-half at home. About 60 were restricted for longer periods because of complications or because of possible continued communicability. The latter was the more usual but often an indefinite reason. Perhaps these patients had enlarged tonsils before contracting scarlet fever, or had crusting of the nasal mucosa without active rhinitis, or other minor irregularities of the upper respiratory tract. From a public health standpoint the program has resulted satisfactorily in that only 1 secondary case of scarlet fever has been detected.

The health of convalescent patients released after 2 weeks' isolation has been determined by the epidemiologist visiting the home 2 weeks after release, and again 1 month later. None of the ordinary suppurative complications of scarlet fever were found. A woman who had suffered from a pituitary condition with complaint of heart attacks for 9 years was of the impression that her cardiac condition had been exaggerated by the attack of scarlet fever, but not to an extent that she called a physician. A second patient had fever and chills 1 week after release due to mastitis following an original puerperal scarlatina.

The appreciable decrease in the length of isolation resulted in no apparent deleterious effect, either clinically

or from the standpoint of the public health.

COMPLETENESS OF REPORTING IN SCARLET FEVER

The equally efficient results with shorter isolation periods suggested investigation of the significant features involved in the present program for attempted control of scarlet fever. There is the immediate objective of determining factors other than age, season, and complications, which may permit additional variations in restriction. It is worth while to examine critically even the actual value of isolation in the control of scarlet fever.

It is fundamentally important to compare the attack rates among contacts to unrecognized and non-isolated sources of infection, with that for contacts of patients restricted by current isolation measures. Determinations have been made of the completeness with which actual cases of scarlet fever are reported and isolated, likewise the frequency and importance of atypical scarlatinal and nonspecific streptococcal infections among immediate contacts. Attempt has been made to determine the number of cases of scarlet fever in a given outbreak, for example, in a school, that can be traced to various kinds of sources: to known cases, to missed cases, to atypical scarlatina, to nonspecific streptococcal disease, and to the agency of carriers.

A study has been made of 1,065 persons with reported and verified scarlet fever, together with their familial, school, and neighborhood contacts, particularly playmates. The number of patients isolated in their own homes was 663, and 402 went to the communicable disease hospital. In addition to the 1,065 reported cases, 253 other persons had an acute febrile illness with sore throat, and either an eruption of the skin, or desquamation, or both; and yet were neither reported nor isolated.

Even with the most careful investigation, all missed cases cannot be determined, particularly among neighborhood and school contacts. The number that was found is probably less than the number that actually occurred.

Familial contacts were observed for illness other than actual scarlet fever during or immediately following the period of isolation. Many had suggestive scarlatinal infection, but without rash or desquamation. The most common condition was sore throat with 180 contacts so affected; 28 are known to have had fever, and 19 vomited. Complications peculiar to scarlet fever were frequent, in about the same proportion as with classical scarlet fever. Table V compares the frequency of complica-

TABLE V
FREQUENCY OF COMMON COMPLICATIONS IN SCARLET
FEVER, AND AMONG CONTACTS WITH UPPER
RESPIRATORY INFECTIONS

Complication	Scarlet Fever Home Isola- tion	Contacts to Scarlet Fever	
		Having Sore Throat	Having Other Upper Respir- atory Infections

Per cent with Cervical Lymphadenitis	15	10	8
Number of patients	663	180	158

* Indefinite because of history of "colds"

tions among these persons, with that for a group of scarlet fever patients isolated at home, and living under comparable conditions. Acute rhinitis and sinusitis was observed 54 times, 5 had suppurative otitis media, and 18 suffered with severe cervical lymphadenitis.

Upper respiratory infections (158 cases), largely of the type of common

cold, formed a second group. Complications such as suppurative otitis media and cervical adenitis were also essentially as frequent as with scarlet fever (Table V). According to available information, the 1,065 reported cases were but a part of the opportunities for spread of the disease. There were, in addition, at least 253 definite and 338 possible sources of infection.

The reaction to the Dick Test was determined for all contacts at the time of report of the original case of scarlet fever. Cultures for hemolytic streptococci were made from the nose and the throat. The tests were repeated 2 months later. Analysis of these data will give pertinent information as to the streptococcal nature of these indefinite infections, the frequency of carriers of streptococci among contacts, and may permit some evaluation of the significance of these groups in the spread of scarlet fever. It is hoped that the presumable change in immunity indicated by an altered reaction to the Dick Test, from positive to negative, may give some idea of the prevalence of subclinical infection.

There is reason to doubt the possibility of controlling scarlet fever by rigorous measures limited to reported cases. This opinion has confirmation in the 1927 report³ of the Committee of Medical Officers of the Ministry of Health, Great Britain, that "the incidence of the disease in the country generally appears to show no marked reduction as the result of hospital isolation, or indeed of any other measure of public control." The extent of the equally important and at present uncontrolled sources of infection justifies for reported cases a minimum requirement in time and method of isolation, which will produce a measure of safety, but not the apparently unattainable end, absolute public protection, which has been the objective of contemporary programs.

PROMPTNESS OF REPORTING IN SCARLET FEVER

Incomplete reporting has been demonstrated, under what is felt to be representative American public health administration. Prompt reporting is equally important. Most secondary cases are infected at the time of onset and during the early days of primary cases of scarlet fever (Table VII). Sig-

TABLE VI
DAY OF ILLNESS THAT SCARLET FEVER WAS REPORTED

nificant delay in reporting can presumably vitiate the effect of an otherwise satisfactory program of control. Representative records of 1,833 primary cases of scarlet fever during 1932 have been examined for the promptness with which official report was made to the Department of Health (Table VI).

The rash of scarlet fever ordinarily appears on or before the 3rd day of the disease. In a sample of 717 cases, 667 (93 per cent) developed within this time. An additional 40 (6 per cent) developed the rash the next day, so that only 1 per cent should have gone unrecognized for longer than 4 days.

Unless there has been a previous case in the family, the identity of the disease can rarely be determined before the rash appears. A report within the first 3 days can therefore be considered as early. About one-half of the cases in the series met this standard. Another 335, (18 per cent) were notified on the 4th day. Certainly not more than 70 per cent can be considered as reported promptly, namely, on the day of the eruption. As an influence on the number of secondary cases, relatively little benefit accrues from isolation which begins after the 7th day. In addition to the 218 cases reported after that time, there were 60 never reported at all, so that the proportion of totally inadequate notification was 15.2 per cent.

THE TIME RELATIONSHIP BETWEEN PRIMARY AND SECONDARY CASES

The frequent delay in reporting original cases naturally suggests that many contacts are infected before the first case of scarlet fever is isolated. Primary cases are often discovered because of a second familial infection.

In 23 instances scarlet fever first appeared in a family when 2 persons developed the infection on the same day. The 2 were considered the primary infection and neither as a secondary case. With this exception, all multiple infections in a family have been interpreted in relation to the one which first appeared. Three hundred ninety-five secondary cases followed the 1,773 primary reported cases (Table VII). Essentially 42 per cent of the secondary

cases occurred before isolation was started, the attack rate being greater for patients isolated at home than for those subsequently sent to the hospital. An additional 95 (24 per cent) occurred within the accepted incubation period of 7 days after isolation was instituted. According to the more usual incubation period of 3 or 4 days, more than three-fifths of all secondary cases were probably infected before isolation or other control was established, and about two-fifths thereafter.

The secondary cases which resulted from infection during the course of isolation were more numerous when the patient remained at home than when isolated in a hospital. Nevertheless, 19 cases occurred among the contacts of patients removed to the hospital in the interval between the end of the maximum incubation period and their return. The number was not appreciably greater when the original patient remained at home (29). This is conclusive that factors other than the patient are active in the spread of the disease. The number is too great to be attributed to chance infection from contact with other cases in the general community. The agency of carriers and missed cases in the family is directly suggested.

The gain from hospital isolation was overcome by the greater number of secondary cases which appeared after isolation was ended, despite the fact that hospital cases were held much longer (Table VII). The information about the number of secondary cases after release of the first, is not to be compared to the ordinary "return case rate" of hospital practice. Whether the patient was isolated at home or in the hospital, careful investigation was made for subsequent scarlet fever, whether reported or not. The data do not merely represent those who came to attention through return of the second case to the hospital or report to the official agency.

Because almost one-half of the secondary cases occurred before isolation was instituted, a more effective program of control through isolation would necessarily emphasize the need for earlier reporting. The weak feature of the home program was in the early days of scarlet fever and suggests a more rigorous program of stricter requirements during that time. The inadequacies of the hospital program are largely centered in the old problem of transmission of infection after the patient returns home. These defects continue to be a pertinent problem despite long isolation or short, despite attempted bacteriological control or stricter clinical criteria for release.

LENGTH AND EFFECTIVENESS OF ISOLATION IN THE HOME COMPARED WITH THE HOSPITAL

Under present conditions in Detroit neither home nor hospital isolation has possessed any essential advantage in efficient control of the disease. There is the important consideration, however, that the hospital group includes many patients who could have been isolated at home only under unfavorable circumstances because of inadequate housing, severity of the infection, or for other reasons.

There were 3,112 susceptible familial contacts to the patients isolated at home and the secondary attack rate was 7.0 per cent. The attack rate for 3,161 susceptible contacts to the hospital patients was 5.6 per cent.

A fairer comparison of the two methods is obtained by eliminating infections which developed previous to isolation. The effectiveness of a particular isolation program can be logically evaluated only by the results which follow its institution. On this basis the attack rates are 3.8 per cent for home isolation and 3.5 per cent for hospital. A number of persons were without doubt already infected when isolation was

started. There is no reason to believe that the number was greater in one group than in the other. If one attempts to correct for those already infected, by eliminating all secondary infections which developed within the succeeding incubation period of 7 days, the ultimate results are then more favorable to home isolation (home, 1.8 per cent; hospital, 2.4 per cent). This is not a justifiable comparison, because a number of the patients eliminated doubtless developed scarlet fever from exposure after isolation, and not through incubating an infection acquired before that time. When the primary case remains at home, infection can come from this person or from other infected individuals; when removed to the hospital, only from others. Such an interpretation thus distinctly favors the hospital group.

Home isolation, where practised, did have the advantage that 71 per cent of the patients were released from isolation at the end of the minimum time. For hospital patients the proportion was only 46 per cent. By the end of the next week essentially 95 per cent of all patients at home had been released, but more than one-fourth of hospital patients still remained in isolation. Many were restricted for 3 and 4 weeks beyond the prescribed minimum. Almost 5 per cent were in the hospital for more than 2 months (Table VIII).

The common reason for prolonged restriction of hospital patients is the presence of complications. They are often more severely ill than those isolated at home and more complications should be expected. Many were sent to the hospital because of complications which had already developed. Nevertheless, the possibility that scarlet fever patients are more likely to develop complications when hospitalized than when they remain at home should have thorough consideration.

Two other explanations can be made

TABLE VIII
TIME OF RELEASE OF 1,787 SCARLET FEVER PATIENTS,
DETROIT, 1932

Time of Release	Home		Hospital	
	Num- ber	Per cent	Num- ber	Per cent
End of minimum	704	71.3	366	45.8
1 week later	228	23.1	216	27.0
2 " "	36	3.6	103	12.9
3 " "	13	1.3	52	6.5
4 " "	3	0.3	28	3.5
5 " "	3	0.3	35	4.4

for the distinct difference in length of restriction between patients of these two groups. One is that the criteria for release are much more strict in hospital than in home practice, where many physicians are responsible for the release of patients, and many, through other interests, are less conversant with minor evidence of complications in scarlet fever, particularly those related to the nose. Probably the private physician tends to be more lenient than the hospital physician, who is directly responsible to the constituted health authority. Whatever the factors contributing to earlier release under home isolation, the significant thing is that it works just as well as the more prolonged hospital isolation.

Griffith⁴ has demonstrated a number of types of streptococci in association with scarlet fever and has shown that under hospital conditions infection with a second or even third type is not uncommon. He has correlated reinfection with the appearance of complications and with communicability after release. This evidence suggests the desirability of emphasis on home isolation where the opportunities for reinfection are minimal.

The convalescence of patients with a similar initial clinical scarlet fever, isolated on the same day of the disease, and restricted according to these two

methods, should be compared under present-day conditions. Housing and other hygienic factors have altered materially since scarlet fever isolation was first formulated. A far greater proportion of patients might now very practicably be isolated at home.

The hospital always will have an important function in the care of patients who offer definite medical problems. It has the equally important obligation to function as a quarantine station when housing conditions prevent adequate home isolation or when the patient is resident in an institution having no satisfactory facilities for segregating such persons. There will always remain in any well conceived program of control an irreducible minimum who should be isolated in the hospital. The extent of this minimum will quite apparently vary with local conditions, but in American cities will not often exceed one-fourth, which is indeed the standard of the *Appraisal Form*⁵ of the American Public Health Association. Nevertheless, with mild scarlet fever, particularly in those cities and in those countries where almost all are now sent to the hospital, there is need to investigate the practicability of isolating at home a larger proportion of the patients. Earlier dismissal of patients who have been hospitalized, particularly if the clinical course has been uncomplicated, appears to be well justified.

CONCLUSIONS

A shorter isolation period for scarlet fever during summer and autumn has been justified by actual trial under field and hospital conditions. The infecting case rate did not increase when adults were isolated for periods as short as 2 weeks, and children for 3 weeks.

Adults with scarlet fever are less likely to transmit the disease than are children. A reduction in the isolation period from 4 weeks to 3 weeks and subsequently to 2 weeks was tried and

showed that the shorter period for adults led to no greater likelihood of subsequent infection among familial contacts. Visits to the patient after release showed that there was no tendency toward development of complications or exaggeration of other medical problems of convalescence as the result of this program.

Approximately 9,000 days of isolation were saved for all patients with scarlet fever in Detroit in 1933. The isolation of adult patients with uncomplicated scarlet fever was decreased by 30 per cent, compared with former practice. Control of the disease was equally satisfactory, judged by the attack rate among contacts and the infecting case rate of convalescent patients. The economic advantage of saving no more than a single week for the thousands of patients with scarlet fever is material.

These experiences in isolation, in the reporting of the disease, and in its communicability, suggest pertinently the development of an altered prescription for satisfactory administrative control of scarlet fever. Such a program should give greater emphasis to home isolation, but provide for adequate hospital care when circumstances are otherwise unfavorable or there is medical need. Hospital isolation should be as brief as possible, consistent with the condition of the patient and the safety of susceptible children at home.

These modifications should be correlated with the type of scarlet fever present. It is probable that in mild climates the restrictions might be reduced further than in temperate climates. When the disease is severe in character, longer periods of isolation may be required.

If much of an improvement is to be expected from isolation as a control measure in scarlet fever it is essential that it be instituted earlier. The present objective is not so much a shortened

isolation time, as one applied earlier and, under home conditions, much more rigorously administered during the period of greatest communicability, the first week. This should make possible an appreciable decrease in the time that patients with scarlet fever are now isolated.

Annual Conference of the New England Health Education Association

THE meetings will be held on Friday afternoon and Saturday, June 1 and 2, at the Massachusetts Institute of Technology, Cambridge. Friday afternoon will be given to inspection of the exhibit put on by cooperating agencies to illustrate methods and materials for teaching health. Mrs. Clair E. Turner will be hostess at afternoon tea.

At the informal supper meeting for members of the Association on Friday evening, Miss Frances Stern, Chief of the Food Clinic of the Boston Dispensary, will speak on "What the Food Clinic Does for the Child," and Miss Mabel C. Bragg, Assistant Professor of Education in the School of Education, Boston University, will discuss and demonstrate the art of story telling. Students in the Fine Arts Course in Framingham Teachers' College will present a puppet play.

In the Saturday sessions, open to the

public, Dr. Wilson G. Smillie, Professor of Public Health Administration in the School of Public Health, Harvard University, will give an account of the present stage of research into the cause of the common cold, and Professor Eduard C. Lindeman, of the New York School of Social Science, will talk on adult health education.

The Honorable Herbert A. Parsons will preside at the Saturday luncheon at the Walker Memorial Building, introducing Dr. S. Monroe Graves, Superintendent of Schools, Wellesley, who will give an account of the work of the State' Committee, of which he was Chairman, and which prepared the Teachers' Manual, recently published on The Effects of Alcohol, Stimulants and Narcotics on the Human System.

The program promises to be of great interest and help to educators and health workers. The program, giving details, will soon be available in print.

Evidence that *B. Alkalescens* (Andrewes) May Be a Variant of *B. Typhosus**

Preliminary Report

RUTH GILBERT, M.D., F.A.P.H.A. (*Life Member*), and MARION B. COLEMAN

*Division of Laboratories and Research, New York State Department of Health,
Albany, N.Y.*

EVERYONE affiliated with a public health laboratory has been confronted by the problem of identifying microorganisms which in many, but not all, of their properties conform to a recognized pathogenic species. When, as in this study, a certain type of culture is found repeatedly under similar circumstances, a special effort to determine its significance seems important. Strains of microorganisms having the properties of *B. alkalescens* have been isolated from approximately 1 per cent of the specimens submitted to the New York State Laboratory at Albany for bacteriological examination for members of the enteric-disease group.

In 1918, Andrewes¹ designated as *B. alkalescens* a species which he described as "an organism simulating Flexner's bacillus but fermenting dulcitol and producing alkali with much vigor." He believed it to be nonpathogenic. In 1928, Smith and Fraser² reported the isolation of *B. alkalescens* from 3 specimens of blood, as well as from the feces and urine of a patient whose symptoms were given as chills, pyrexia, grossly distended abdomen, diarrhea, and marked generalized icterus. Weil³ isolated this microorganism from the urine, and be-

lieved it to be the incitant, in a case of cystopyelitis. Popoff⁴ reported an interesting case of pyelonephritis apparently due to infection with *B. alkalescens*. Mackenzie⁵ of Montreal, at the meeting of the American Association of Genito-Urinary Surgeons in May, 1933, discussed the isolation of *B. alkalescens* from the blood of a patient having symptoms of typhoid fever and evidence also of pyelonephritis.

The strains designated as *B. alkalescens* are Gram-negative, nonmotile bacilli. Neither capsules nor flagella have been demonstrated. They develop readily on infusion and extract agar, producing smooth, colorless, convex colonies, with entire edges, somewhat less translucent and heavier than those of typical typhoid bacilli. On Endo's medium and eosin methylene-blue agar, the colonies may have very small red and blue centers, respectively. Their growth is usually inhibited on brilliant-green agar. The other characteristics in which they differ from *B. typhosus* are: the formation of acid in media containing rhamnose and dulcitol, the production of indol, and a definite alkaline reaction in litmus milk following an initial acidity. The reaction in double-sugar medium is the same as that of *B. typhosus* or *B. dysenteriae*; that is, acid forms in the butt and the slant is colorless.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

In a study of the serological reactions, no appreciable agglutination in typhoid antiserum has been obtained with strains having the properties of *B. alkalescens*. It may be of significance that this is the first property to be lost in the case of strains of *B. typhosus* grown in broth containing typhoid antiserum.⁶ Sera from rabbits immunized with *B. alkalescens* have given very irregular agglutination in tests performed with living cultures, but have consistently agglutinated alcohol treated suspensions of strains of the homologous species. Similar reactions have been obtained with precipitation tests. The alcohol treated suspensions of *B. alkalescens* are also agglutinated in polyvalent dysentery antiserum. A further study of this phase of the problem is planned.

Most of the characteristics of *B. alkalescens* have been observed individually in certain otherwise typical cultures of *B. typhosus*. Nonmotile strains of the latter, although extremely rare, have probably been encountered by most bacteriologists who have examined large series of specimens from patients with typhoid fever. Strains which are inagglutinable, at least when freshly isolated, are more frequently found. Flexner,⁷ in 1894, reported a so-called "blue" strain of *B. typhosus* which, after preliminary formation of acid, produced a marked alkaline reaction in litmus milk. Penfold^{8,9} found that *B. typhosus* may be induced to ferment rhamnose and dulcitol by cultivation in media containing these carbohydrates. The production of indol by certain cultures belonging to this species has been reported by Peckham.¹⁰ The results⁶ of experiments which as yet we have been unable to confirm, indicate that certain strains of *B. typhosus* cultivated in medium containing typhoid antiserum may assume the biochemical and antigenic properties of *B. alkalescens*.

The infrequency with which *B. alkalescens* is isolated warrants the assumption that this species is rarely present in the intestinal flora. During the period January 1, 1931, to July 1, 1933, in the examination of 10,747 specimens of feces, urine, and blood for *B. typhosus* and other incitants of enteric disease, cultures having the properties of *B. alkalescens* were found in 119 specimens from 49 persons; they were isolated from both feces and urine, but have not as yet been obtained from blood. In addition to the strains which we isolated, 15 cultures were sent to us for identification by directors of other laboratories in New York State. Twenty-nine of the individuals from whose specimens this species was obtained had, or were convalescent from, typhoid fever; 13 others had gastroenteritis. (These 2 groups include 65 per cent of the 64 persons represented.) Two were carriers of *B. typhosus* and 17, 4 of whom had a history of enteric disease—probably typhoid fever—were being examined for evidence of the carrier condition. One of the 3 remaining patients had cystitis, and pertinent data did not accompany the specimens from the other 2. In 5 instances, these microorganisms were found in specimens from 2 or more individuals in the same family. In 5 other cases, when this species and no typhoid bacilli were found in specimens from patients with, or recovering from, typhoid fever, *B. typhosus* was isolated from specimens from other members of the same household who were ill or who had had typhoid fever within a period of a few months.

Pertinent information concerning 8 of the typhoid fever patients, which has been summarized in Chart I, seems of interest. Cultures of both *B. typhosus* and *B. alkalescens* were isolated from specimens from these individuals. The 8th case is of particular interest since it represents a laboratory infection.

● B. TYPHOSUS ISOLATED
 ▲ B. ALKALESCENS ISOLATED
 ○ NEITHER ISOLATED

The patient had been handling cultures of both species. Although typhoid bacilli were readily obtained from this patient's blood during the first 2 weeks of illness, they were isolated with difficulty from the early fecal specimens, while *B. alkalescens* was apparently present in relatively large numbers. Later, both types were numerous, and, finally, neither was found. ...The significance of *B. alkalescens* in this case can only be conjectured. Its presence previous to the illness is unlikely, since it persisted and disappeared at practically the same time as the typhoid bacilli. One of 2 conclusions is suggested: a strain of *B. alkalescens* may have been the incitant, which, after entering the body, developed into a true typhoid bacillus, or, if *B. typhosus* were ingested, the other species may have been its variant.

SUMMARY AND CONCLUSIONS

It has been shown that strains of bacteria having the properties of *B. alkalescens* are present in approximately 1 per cent of all specimens submitted for bacteriological examination for evi-

dence of enteric disease. Clinical and epidemiological data suggest a close relationship to the typhoid bacillus.

In the study of specimens from patients recovering from typhoid fever and in the search for carriers, the presence of this type of microorganism seems of special import. Even though, in itself, it may have no pathogenic significance, the fact that in so many instances *B. typhosus* has been isolated from the same or other specimens from the individual concerned, makes a thorough search for this microorganism imperative, whenever strains of *B. alkalescens* are found. When suspected typhoid carriers are concerned, it would seem very important to examine a large series of fecal specimens and, if possible, duodenal contents.

Practical Method for Public Health Laboratory Diagnosis of Infectious Syphilis*

HERBERT E. McDANIELS

Research Laboratories, State Department of Public Health, Chicago, Ill.

PRE-WASSERMANN diagnosis of syphilis is of great value from at least two standpoints. First, as has been repeatedly pointed out by venereologists, an early diagnosis followed by adequate treatment offers the patient the greatest possibility of complete cure—the so-called “abortive cure.” Second, from the public health point of view, the sooner a case of syphilis is diagnosed and reported, the more efficiently can the health department apply its supervisory control.

A graph (Figure I) prepared from percentages reported by Owen and Cope¹ on 1,061 proved cases of primary syphilis gives a good index of the superiority of the darkfield test over serological tests. It will be seen that the latter tests do not equal the darkfield method in efficiency until the third week of the disease.

Other tests on secretions from sus-

pected lesions are either unreliable, unsatisfactory, or impractical for one reason or another. Fortunately the practice of making a diagnosis from the clinical appearance of a sore has been shown to be so unreliable that it has

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

been abandoned. Among the remaining methods applicable to chancre secretions are stained preparations, contrast methods, or serological tests. Preparations in which material from the suspected chancre is smeared on slides or cover-slips for the detection of *Treponema pallida* by means of stains are definitely inferior to the darkfield test. The organisms are usually distorted in the smearing and drying process, and if a silver impregnation method is used, there is further swelling and distortion of the actual appearance of the organisms. India ink contrast preparations require considerable skill, and if one has in mind the sending of chancre fluid to a laboratory for this purpose, it would be more satisfactory to use the fluid in a darkfield test. Because of the earlier local development of reacting substances, it is possible to utilize chancre fluid in complement fixation or precipitation tests. The technical difficulties involved in the collection and sending of enough suitable fluid for this purpose are such as to make this method impractical.

Undoubtedly the best conditions for the darkfield examination of lesions suspected of being syphilitic are those in which the patient goes to a laboratory or special venereal clinic and remains until satisfactory test material has been examined. The material is freshly collected by an experienced worker and the patient is available if retests on more of the secretions are desired. There is, however, a large field for a test which would be available to physicians practising in rural communities and in small towns where there are no laboratory facilities. Also patients unable to pay for the services of a venereal specialist and unwilling to go to free clinics and dispensaries would benefit by a test which could be collected in the doctor's office and mailed to a state or municipal laboratory. Such a service should be offered by public health or-

ganizations because the early diagnosis of syphilis is distinctly in the field of preventive medicine.

Mahoney and Bryant,² experimenting with material from rabbits and also from human lesions, found that recognizable treponema persisted in collected specimens for 4 to 5 days in most cases. They used straight capillary tubes, filling them by capillarity and sealing with a paraffin-vaseline mixture. A progressive decline in motility of the organisms was the usual finding in the collected material. Temperature of storage was an important factor, they found; tubes kept at higher temperatures became unsuitable or negative in darkfield tests sooner than those kept at lower temperatures. This was interpreted as being due to the effect of the bacterial over-growth which was more pronounced at the higher temperatures.

Our efforts have been directed toward the development of a method which will permit of the collection of serum from chancres in such a manner as to afford optimum conditions for the survival of recognizable treponema. The method must be simple enough to be readily understood and the completed package must be such as to withstand rough handling in the mail. Postal laws and regulations also had to be taken into consideration.

An outfit which has been satisfactory in our hands, and which has been approved by the district supervisor of parcel post, consists of a one-piece stamped iron box, 6.5 x 2.5 x 1 cm. with a slip-cover to fit; paraffin-vaseline mixture, capillary tubes, identification card, and the usual screw top mailing tube. The capillary tubes are 5 cm. long and of about the same thickness and bore as the tubes in which smallpox lymph is ordinarily dispensed. Three of these capillaries are sent out in each outfit, placed in a small glass test tube, with cork stopper for protection against breakage. The small iron boxes are

half filled with the paraffin-vaseline mixture which is then allowed to harden. The percentage of paraffin is varied to suit the seasonal variation in temperature—approximately 10 per cent paraffin is suitable for all but the hottest weather.

To fill the capillary tubes, the doctor secures an exudation of clear serum on the lesion and applies one end of the fine tube to the fluid. We recommend holding the capillary in a horizontal position for assisting the capillary flow, and also request the filling of more than one tube as a safeguard against drying which occasionally takes place. When the specimens have been taken into the tubes, the latter are placed on the surface of the grease in the box and gently pressed beneath the surface. This seals both ends of the capillaries and at the same time provides support and protection for them in transit.

To examine the specimens at the laboratory, the tubes are removed from the grease with forceps and the contents expelled by repeatedly pressing one end of the tube into a stiffer paraffin-vaseline mixture until the fluid is driven out of the other end of the capillary onto the darkfield slide. A point of practical value, in the laboratory at the time of preparing the slides, is to allow a small amount of the grease which adheres to the capillary to drop on the slide. This serves to anchor the cover-slip at the center and to prevent sudden currents in the preparation under the microscope.

Through the coöperation of two venereal clinics in Chicago, we have received known positive material from cases of primary syphilis. These specimens were sent by mail so that the effect of such handling would also enter into the trial of the method. Additional advantages in this arrangement were that the time of placing the specimens in the capillary tubes was known and also the approximate abundance or

scarcity of treponema was in most cases indicated on the information card.

The results of these preliminary tests may be summarized briefly by tabulation (Table I).

TABLE I

RESULTS OF DELAYED DARKFIELD TESTS				
Days elapsed	No. of Specimens	Positive	Negative	Dried-Out
1	57	56	1	0
2	42	35	5	2
3	14	12	0	2
5	1	1	0	0
6	1	0	1	0
Totals	115	104	7	4

Of the total of 115 examinations, 104 or 90 per cent were found to be positive after 1 to 3 days from the time of collection. Two specimens were delayed in transit and were received 5 and 6 days after the material was collected. The first of these was still positive, but the 6 day old sample was negative. The specimens which dried out in transit did so because the capillary tubes were not forced below the surface of the paraffin-vaseline mixture.

A positive diagnosis in this series of tests was based on the presence of treponema of characteristic form. As reported by Mahoney and Bryant, we noted in general a progressive decline in motility. This question of motility was not a perfectly regular function of the age of the specimens, however. Many of the 1 day old tubes contained organisms which were non-motile, and occasionally actively motile forms were found in 2 and 3 day old specimens; but the usual experience was that motility decreased with age.

The presence of other spiral organisms was noted in many of these specimens, but they did not interfere with the survival of *Treponema pallida* in a recognizable form. Too many red blood cells in a darkfield preparation render the examination difficult, but it

is our impression that there was better preservation of motility and form in specimens which contained a few to a moderate number of red cells. Whether this was accomplished through the production of a more favorable oxygen tension or whether it was due to other causes is not known. In the routine use of this delayed darkfield test, it should be especially emphasized that a negative finding does not exclude syphilis in the patient. Retests are indicated on all negative results.

Our Changing Diet

OF all the midnight marsh glows that civilized or semicivilized man has followed in his pursuit of the true light that would lead to complete and permanent health, the most have been built about his diet. True, his diet has changed as he and his environment have changed, and certainly not always for the better. The focus has shifted from calories to ash and from ash to vitamins, and has rested on those mysterious substances to be found in liver and the gastric glands, until it has seemed almost as if the lowly tripe were at last to come into its own.

From the wheat lands has come a

paeon of glory in favor of crumbled toasties, and from the plantations of the citrus growers a trumpet note has sounded the knell of acidosis. Still, it must be believed, we are coming nearer to a true understanding of the metabolism of digestion; of man's wants and of the deficiencies which he has imposed upon himself. We are realizing at last that those foods which are nearest at hand, which are most edible in their natural state and which require the least preparation and processing are the best suited to our needs.—Joseph Garland, Dental Health. *New Eng. J. Med.*, Mar. 15, 1934, p. 570.

Standard Methods and New Procedures for the Isolation of Colon Bacilli from Water*

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A.

Professor of Public Health, Yale School of Medicine, New Haven, Conn.

THE isolation of *B. coli* † from water dates back at least to the work of Theobald Smith (1893) 40 years ago. Glucose broth was used at first but later it appeared that lactose broth was preferable since it cut out many forms unrelated to the colon group which ferment glucose but not lactose. In the second edition of *Standard Methods* (1912) a lactose-bile presumptive test was recommended for the "colon group" as a whole; and preliminary cultivation in glucose or lactose broth with isolation on litmus-lactose-agar and identification by various tests, for *B. coli* itself. In the third edition (*Standard Methods*, 1917) there was outlined the procedure which has been essentially followed up to the present day.

This procedure as set forth 16 years ago involved the inoculation of lactose broth fermentation tubes as a presumptive test with plating on Endo medium or litmus-lactose-agar as a partially confirmed test and with isolation of pure cultures and testing for

lactose fermentation and morphology as essential for a completed test. In the fifth edition (*Standard Methods*, 1923) eosin-methylene-blue was substituted for litmus-lactose-agar as an alternative to Endo medium for plating from positive lactose-broth presumptive tests. Otherwise no change was made in basic procedure until the present year. From 1917 to 1933 it was allowable to perform the lactose-broth presumptive test only, in routine examination of raw waters in connection with control of the operation of purification plants and the partially confirmed test only "in the routine examination of water supplies where a sufficient number of prior examinations have established a satisfactory index of the accuracy and significance of this test in terms of the completed test."

Meanwhile numerous efforts had been made to replace lactose broth by some medium which would be so specifically adapted to *B. coli*, and to this organism alone, that a single test for gas formation might serve as the final criterion of its presence. Among the earlier procedures were the use of bile media, of phenol broth, of media containing neutral red, of aesculin media, of liver broth and cultivation at 46° C. References to these earlier studies are given in detail by Prescott and Winslow (1931). Most of them have been abandoned; but the Eijkman test (in-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

† Throughout this paper the term "*B. coli*" is used for the entire colon group, including both *Escherichia* and *Aerobacter*. The differentiation between these two forms is not here considered though it has very real importance. Parr and Caldwell (1933) found that the organisms cut out by the use of brilliant-green bile were chiefly of the *Aerobacter* type.

volving cultivation at 46° C.) has recently been studied by Leiter (1929), Brown and Skinner (1930), and Perry and Hajna (1933); and bile still plays a part in some of the more recent media.

The possibility of utilizing inhibitive dyes in selective media for the isolation of *B. coli* received a powerful impetus from the work of Hall and Ellefson (1918) with gentian violet. Bronfenbrenner, Schlesinger and Soletsky (1920) suggested the use of rosolic acid and Muer and Harris (1920) that of brilliant green. Dunham, McCrady and Jordan (1925) and Jordan (1927) obtained good results with a medium containing both brilliant green and ox gall. Both reported over 90 per cent correlation with the standard procedure. Noble (1928) developed an agar medium containing potassium ferrocyanide, ferric citrate, fuchsin and sodium sulphite. Salle (1929, 1930) experimented with crystal violet and Dominick and Lauter (1929), Salle (1930), and Leahy (1930) with brom-cresol-purple media. Ritter (1932) reported highly encouraging results from Kansas with standard lactose plus 0.8 c.c. per liter of saturated alcoholic basic fuchsin. Out of 33,532 positive presumptive tests in this medium, over 94 per cent were confirmed as *B. coli*. In a series of 533 samples run in parallel the average coli index after confirmation was essentially the same in both media; 17 per cent of the samples showed a higher index in standard broth, 16 per cent a higher index in fuchsin broth. Jordan (1932), a year ago, presented a review of the brilliant green procedure which led to a stimulating discussion.

As a result of all this agitation the Committee on Standard Methods in its seventh edition at last recognized that something had happened since 1917. It provided (*Standard Methods*, 1933) that for "unfinished waters," duplicate inoculation into lactose broth and

brilliant-green bile might be employed, with transfer to a secondary tube of brilliant-green bile from any positive primary lactose tube paralleled by a negative primary brilliant-green bile tube. This shortens the test time to between 24 and 96 hours for this class of waters. It is still permissible to rely on a presumptive lactose broth test alone in the case of raw waters subject to purification processes; and it is still necessary to follow out the old routine of isolation and identification for all waters assumed to be potable.

During the past 6 months several important new contributions to this subject have appeared. Nolte and Kramer at St. Louis (1933) found Noble's cyanide-citrate agar unsatisfactory; but Dominick and Lauter's methylene-blue brom-cresol-purple broth gave admirable results. Less than 5 per cent of the lactose-broth presumptives were confirmed as compared with over 76 per cent of the Dominick and Lauter presumptive tests. Furthermore, the Dominick and Lauter medium yielded more confirmed positive isolations than the standard lactose medium (11.4 per cent against 8.9 per cent for unfinished waters and 1.1 per cent against 0.9 per cent for finished waters).

Butterfield (1933), on the other hand, takes a vigorous stand against the use of simplified methods except as permitted by the new edition of *Standard Methods*. He reports new data (for Cincinnati waters) showing that brilliant-green bile gave only 84-90 per cent of the final completions obtained with *Standard Methods* on raw waters and only 35-37 per cent with finished waters. The Dominick-Lauter method was even more unsatisfactory. Butterfield then analyzes the results presented by Jordan (1927) and shows that while on the average for all samples brilliant-green bile (with 2 per cent ox gall) used as a complete test,

gave over 80 per cent of the completed positive tests yielded by *Standard Methods*, the proportion fell to 56 per cent for one source (Cincinnati). Only one other source, however, fell below 70 per cent. The apparent difference between Butterfield's results and those reported by others is, of course, due to the fact that he computes his results in per cent of Standard Method-positives, which are also brilliant-green-bile positive, while most summaries have presented merely the per cent of all samples positive by each of the two methods. Thus, if lactose broth shows 8 per cent of samples positive with lactose broth and 4 per cent with lactose bile, most reports would suggest a close agreement (92 per cent negative by both tests, 4 per cent positive by both tests, 4 per cent divergence). Butterfield would say that the method showing 4 per cent positives was 50 per cent in error.

Still more recently Stewart (1933) has reported favorably on the Dominick-Lauter method, and Parr and Caldwell (1933) have presented a new study of brilliant-green bile. Full data are given for 1,407 samples with the following results: Lactose-broth presumptive tests were positive for 82 per cent of all samples while only 43 per cent of the primary brilliant-green bile tubes were positive. Colon bacilli were confirmed after lactose-broth enrichment in 32 per cent of all samples, after brilliant-green bile enrichment in 24 per cent of all samples. Thus, if the confirmation according to *Standard Methods* be taken as a norm, the brilliant-green presumptive gave, in this instance, results which were 23 per cent too low. These samples (for Alabama wells) contained a large number of anaerobic organisms producing a false-positive reaction in brilliant-green bile.

We may summarize the general situation by saying that the brilliant-green bile medium (which has been most exhaustively studied), when used without

any confirmatory procedure, gives us on the average about four-fifths as many positive results as the *Standard Methods* with complete confirmation. Media employing crystal violet, basic fuchsin and, particularly, brom-cresol-purple have also yielded highly encouraging results.

If this were the whole story, the argument for adopting a simplified procedure would be practically conclusive. It sounds impressive to say that the brilliant-green bile test yields only three-quarters or half as many positive results as *Standard Methods*; but such a difference as this has no very great practical significance when interpreted from a practical quantitative standpoint. No sanitarian can rationally condemn a water which shows 8 per cent positive results, and pass one which shows 4 per cent. Actually, of course, we work in powers of 10 in making our dilutions, and even such extreme variations as those recorded by Butterfield would only influence one's decision in a few borderline cases. The loss of one-fifth of the colon bacilli present could not conceivably have any real influence on the practical conclusions to be drawn.

Furthermore, if there were even a greater difference than anyone has suggested, this difference—if it were reasonably uniform—could be allowed for by a change in standards of interpretation. Neither the colon test nor the Treasury Department Standards form part of any law handed down on tables of stone from Sinai. If it seemed more convenient to use a procedure which gave only half as many colon bacilli as the present *Standard Methods* we could quite easily set a limit of one positive 10 c.c. portion in 20 (instead of 1 in 10) as our limit of safety.

The only aspect of the situation which gives one pause is the possibility that marked and really significant differences may exist between different

waters. If it be true that Cincinnati treated waters tested with brilliant-green bile show only 35 per cent as many positives as *Standard Methods*, while with other waters the ratio rises to nearly 100 per cent, the problem is more serious.

Even so, however, the question is by no means closed. We need to know the reason for the differences. Does the Cincinnati treated water contain a large proportion of attenuated colon bacilli which are really of slight sanitary significance? Do the Alabama wells contain anaerobic spore-formers of the *Cl. Welchii* type, which may be much more important than attenuated *Esch. coli*?

We have used the colon test in its standardized form so long that it has become something sacred and untouchable; and that is always a dangerous frame of mind smacking of religion rather than of science. Let us remember that this is a test devised by plain human beings like ourselves and that it was designed to differentiate between safe and unsafe water supplies. The colon bacillus in itself has no inherent significance except as an index of sanitary quality. The isolation of all the colon bacilli present is of no importance except as an index of sanitary quality. What we want is a test which shows the greatest possible difference between good waters and bad waters; and that is all we want. It is quite possible that where the newer bile-dye media yield results different from those of *Standard Methods*, they may be more significant than *Standard Methods* and not less. They appear to give higher results with more polluted waters, and lower results with less polluted waters, which is exactly what we want in a yardstick of this kind.

The standard procedure for isolating *B. coli* has two serious defects. In the first place, it permits the use of lactose-broth fermentation as a final and com-

plete test for raw waters in connection with the operation of purification plants. This is a test which yields results which are often far too high, since certain waters rather regularly contain spore-formers or combinations of symbiotic organisms which are of no sanitary significance but yield positive results. Thus, the efficiency of purification processes is greatly overestimated.

In the second place, *Standard Methods* requires for all waters in a potable state the old complex process of isolation and identification which consumes 6 or 7 days and an enormous amount of time and materials. The procedure was the best available in 1917. It seems to the writer to be archaic and indefensible in 1933.

There seem to be two possible alternatives which are clearly suggested by the progress made in the study of new methods during the past 10 years. The first of these alternatives is the use of simultaneous inoculation into lactose broth and brilliant-green bile with secondary inoculation into brilliant-green bile from positive primary lactose tubes paralleled by negative primary brilliant-green bile tubes. This is the procedure now permitted for unfinished waters; but there seems no valid reason why this type of procedure should not be accepted for all classes of waters. Even Butterfield's analysis shows that this procedure yields on the average 95 per cent of the positive results obtained by *Standard Methods*. He is disturbed by the fact that in results from 4 out of 15 cities the ratio falls below 90 per cent—the figures being 89 per cent for Omaha, 87 per cent for Indianapolis, 86 per cent for Montreal, and 71 per cent for Chicago. It is really difficult to see how such results can be considered as unsatisfactory if one lifts his eyes for a moment from the laboratory table and considers what the colon test really means, the actual uses to which it is put, and the limits of accuracy

within which it can conceivably be interpreted.

Personally, I hope and believe it should be possible to go even further than the general adoption for all waters of the double inoculation into lactose broth and brilliant-green bile. There are several of the new tests (particularly the brilliant-green-bile and brom-cresol-purple media) which seem to offer excellent promise of a single primary fermentation test which could be accepted as final for all classes of waters. For supplies from most regions it seems possible by such procedures to obtain four-fifths as many colon bacilli as by the use of *Standard Methods*; and such a result is well within the range of practical interpretation.

The fact that certain waters when tested by such procedures show divergent results, some higher than when tested by *Standard Methods*, some considerably lower, may be a real disadvantage. On the other hand, it may be an advantage. The use of lactose-broth tubes followed by isolation and identification has, after all, no Divine sanction. It may be that the newer procedures correspond more closely than the old ones to actual sanitary conditions.

My plea is for a fundamental re-examination of this whole problem with an open mind, and with a clear view of the practical results to be obtained, and of the margin of error associated with their interpretation. The pressing need for economy and efficiency makes such a re-examination peculiarly imperative at the present time. If we can cut down the cost of an examination we can make more examinations; and a fuller measure of control should vastly outweigh any 5 or 10 per cent loss in accuracy.

I would therefore urge upon the Laboratory Section the adoption of definite steps along somewhat the following lines.

1. The bacteriologists associated with the Standard Methods Committee should first make a preliminary survey of the field and select three or four of the most promising of the new procedures (such as the use of brilliant-green bile, brom-cresol-purple, crystal violet and basic fuchsin media or cultivation at 46°). The methods selected should include 1 or 2 which involve the use of a single confirmatory medium following lactose-broth fermentation, and 1 or 2 which involve the use of a single primary selective medium by itself.

2. A considerable group of collaborators should be enlisted to make comparative tests of water samples from various sections of the country, raw waters and finished waters, filtered and chlorinated waters, well waters and surface waters. These collaborators should employ for each sample: (a) *Standard Methods* with full confirmation, (b) one or more methods employing a single confirmatory test following lactose-broth fermentation, and (c) one or more methods employing a single primary fermentation test alone. The work involved need not be very great. For instance, each sample might be inoculated into lactose-broth, brilliant-green-bile and brom-cresol-purple broth. All positive lactose-broth cultures which were negative in either of the other media should be inoculated into a secondary tube of that medium; and all positive lactose-broth cultures should be followed through by *Standard Methods*. The procedure set forth by the central committee for each test should be strictly followed. Records of sanitary inspection should be available to give an idea of the probable sanitary quality of each water.

3. The Central Committee of Bacteriologists associated with the Committee on Standard Methods should assemble all results, and compute comparative averages in various ways for

various classes of waters. Those waters which yield markedly divergent results by various methods should then be studied in detail by obtaining data as to their real sanitary quality.

Such a program, if vigorously prosecuted, should make it possible in 2 years' time to arrive at reasonably definitive results. I believe it would open the way to new *Standard Methods*, in accord with the recent progress in water bacteriology, and not only more efficient and more economical but more significant than those now employed.

The Laboratory Section is the logical body to take such a step. If it fails to do so, some other group is likely to take the initiative, for, to many of us, the present situation seems well nigh intolerable.

DISCUSSION

C. J. LAUTER

Sanitary Engineer, Filtration Plant, Washington, D. C.

AT the 1932 meeting of this Section I had the opportunity to say a few words on the merits of the MB-BCP medium, which I wish to discuss more fully. I am looking at the isolation of the colon-aerogenes group in

water works practice, purely as a laboratory worker and representative of the thousands of water works laboratories and superintendents where the bacteriological analysis of the processed water is necessarily only a part of the

daily duties of the filter plant operator, and as one who has tried the lactose broth routine and has found it wanting.

Accuracy and detail should not be sacrificed to gain time. It was with this point in mind that Hale, of New York, advocated so long the brilliant bile medium upon which an extensive series of studies was done under the leadership of Mr. McCrady, our chairman. This was followed by the work of Jordan, of Indianapolis, and has resulted in the use of a final or confirmation tube of brilliant-green bile being allowed in the 1933 edition of *Standard Methods* as an alternate method.

The work in our laboratory for the past 5 years has been chiefly devoted to the use and development of the MB-BCP medium, which is being run in parallel with standard lactose broth on a large part of our daily routine samples.

The 3 series given on the table were made on 52,000 tubes, over a period of 18 months, on 3 distinct classes of water, namely, raw or river and coagulated; filtered without chlorination; and chlorinated filter effluent.

There are 3 distinct sets, each using a variation of the medium as follows: Series "A" was made on a dehydrated medium according to the first formula used, designated A in table. Series "B" was also a dehydrated medium, in which the dye content was cut, but in which the beef extract was also cut to a very low point. Series "C" is the same as "B," with 5 gm. of beef extract and .025 gm. methylene-blue per liter added to enrich it and prevent, if possible, some of the losses encountered in "B."

The results have been enumerated separately on each class of water and then taken collectively for each group. It is evident that "A" is good, "B" less efficient in recovery than "A," and "C" almost perfect, that is, from the standpoint of standard lactose performance.

The lactose broth tubes were all confirmed in accordance with *Standard Methods*, and the MB-BCP for a great part was confirmed in the same manner, although this was dispensed with for a while, as results of over 1,000 tubes showed better than 99 per cent confirmations on all types and dilutions where gas was formed in 24 or 48 hours.

If we grant that we lost 1 tube in Series "C" in the 1 ml. dilutions over 4 months, and 1 tube after 6 months, we might argue that the medium is defective; yet we have a gain in the 10 ml. portions at other times, thus manifesting its superiority, and indicating that at least a part of the losses in the 1 ml. dilutions are due to distribution of a few organisms present over the range of the tubes made.

Of what significance is the loss of 1 tube in any water over 4 months, when in the raw water we are able to pick up more tubes in both 1 and 10 ml. dilutions, and in also 0.1 ml., which is not here shown. Most of these show gas on the first day, and the plant operator, be he a chemist, bacteriologist, or engineer, can easily see gas formation and the accompanying color change and draw his conclusions almost before the water leaves his plant.

We do not claim to have found an infallible means of differentiating *Escherichia coli* from *Acrobacter aerogenes*, but do feel that it is something that can be used by a trained scientist and an unskilled plant operator with practically the same efficiency and within a time which will allow the use of the results before the water is used by the consumer.

This latter claim has been verified a number of times in our city in the case of outlying reservoirs where the colon-aerogenes group was detected in 24 hours in normally colon-free water, treated and rectified, after which we were notified by other sources that the group existed in this reservoir.

In addition to the MB-BCP we also ran a great number of 2 per cent BGB tests in parallel.

We were at a loss to explain the poor efficiency of this 2 per cent BGB as we had been getting almost parallel results with lactose broth in the past. The 5 other BGB figures were on Special BGB 2 per cent media, of varying brilliant-green concentration, kindly furnished by Mr. Dunham of the Difco Laboratories. Little has been done on this medium for the past 6 months as we felt that the MB-BCP has a slight edge on it and certainly was better than lactose.

The color reaction is a big thing in its favor and from this alone one can get some idea of the recency of pollution or degree of attenuation. The reaction goes from blue, to purple, pink, orange, yellow, then to green. The last two are practically always accompanied by gas in 24 hours or less, although 48-hour tubes will also show this color.

Those organisms very strongly attenuated may take 48 hours to give gas and the medium is generally pink in color. Negative tubes remain blue or purple or sometimes pink, but with no gas.

It is on the following point that most of the criticism may arise. In pure culture work, a medium, designed to do a certain thing for natural waters, will not function 100 per cent, nor is it necessary that it should. In pure cultures the organisms used are not typical of those encountered in the water sample:

1. Because they have had a different environment. In the filtered-chlorinated water they have resisted the attack of several tenths p.p.m. of chlorine and are therefore less able to overcome the inhibitory effect of the dyes in the medium, than in their revived state.

2. The concentration used in pure

culture is often many times the amount that is encountered in the water sample. Therefore, the dyes necessary to inhibit the pure culture laboratory strain and concentration must be greater than the amount necessary to inhibit those met with in practice. This is shown in our own laboratory, where it has been found that a certain strain of an aerobic, Gram-negative, lactose splitter will not give a positive reaction on MB-BCP medium, although positive in standard lactose broth. It will, however, give a beautiful positive reaction when introduced in mass culture. There is obviously no means of comparison here.

The cost consideration should not escape us. These 3 series of runs were accounted for on the basis of dehydrated medium which was the material used, and eliminating the extra time required for making the EMB plates and the greater number of tubes of primary and secondary lactose tubes, we have:

Materials only, Standard Lactose	
Broth. Complete	\$159.00
Materials only, MB-BCP Medium.	
Complete	106.00

Thus we have a net saving on material *alone* of \$53 or 50 per cent of the cost of BCP. To a large laboratory this may and does mean a considerable item, and in addition the time saved will allow more valuable work to be done and more money spent in research for the ultimate discovery of the perfect medium for this elusive family of organisms.

Before concluding, I want to recall the work done on this media by Leahy and his associates, working at Rochester; Lieutenant Commander McCants of the U. S. Naval Medical School, where it is being used as the medium best adapted to the conditions of the Naval Service; Aug. G. Nolte at St. Louis; H. V. Stewart, Director of

THREE SERIES OF COMPARATIVE RUNS ON STANDARD LACTOSE BROTH AND METHYLENE BLUE BROM CRESOL PURPLE MEDIUM

These tests are the daily routine of the Dalecarlia Filter Plant, Washington, D. C., from Feb., 1932, to Aug., 1933

Compiled Sept. 27, 1933—C. J. Lauter

the Hygienic Laboratory at Little Rock, Ark., H. E. Jordan of Indianapolis, and Mr. Howard of Toronto, Canada.

Leahy, McCants, Nolte, Stewart, Jordan and Howard seem favorably inclined to this or some sort of rapid means of colon-aerogenes isolation, and have found the MB-BCP medium unexcelled by standard lactose broth. Mr. Dominick and I present this medium

as a substitute for the present lactose broth method, and for further study. We advocate its use as a "direct inoculation" medium, and that all gas in 24 and 48 hours be accepted in plant routine as positive for members of the colon-aerogenes group, thus developing an actual bacteriological control of the filtering process, instead of the present chemical control only.

HARRY E. JORDAN, F.A.P.H.A.

Filtration Engineer, Indianapolis Water Company, Indianapolis, Ind.

I HAVE the following comments to make upon the subject under discussion:

1. Variations in diagnostic procedure for coli-aerogenes group based upon stage of treatment of water are undesirable. The use of presumptive lactose alone on raw waters increases the apparent density of coli and by the application of the complete test to finished waters exaggerates the apparent efficiency of the purification process.

2. The use of inhibitive media for primary planting (to the exclusion of lactose broth) produces a deviation from previous data material enough to support the contention of conservatively minded that significant forms are being excluded. While I have a degree of sympathy with the contention of Dr. Winslow that we should reconstruct our interpretative procedure in terms produced by the simplified technic, I doubt that the gain is worth the argument it

would cause. One can easily assume that, in the case of the U. S. Treasury Standard, the per cent of 10 ml. positive portions could be reduced to 7 or 8 instead of the 10 per cent now allowed. I do not believe that many plants now complying with the standard would be discredited by the change. Performance among the majority appears to lie under 5 per cent positive findings as the water is delivered by the purification plant to the municipal distribution system. But until the Treasury Department through its Public Health Service indicates a desire to revise the present standard, standard laboratory procedure must continue to approximate the procedure set up in the Fifth (1923) Edition of *Standard Methods*. The necessity of coördination limits the present editorial committee to the promulgation of methods of evaluating coli-aerogenes density which will meet the requirement of statistical equivalence or approximation. Incidentally, this, along with various other reasons, would appear to raise the question of need of revision of the Treasury Standard.

3. I am firmly of the opinion that methods of determining coli-aerogenes group presence should be adapted to the production of more data regarding density of the group—especially in raw waters. Many laboratories do not examine enough portions of finished water to obtain a true density picture. There is not a treated surface water in America that does not contain organisms of the coli-aerogenes group, and they can be found if large enough quantities of the supply are examined. While it would not be practical to recommend the regular examination of enough water each day to produce a positive finding, a step can well be taken in that direction by the addition of 100 ml. portions to the finished water routine.

On the other hand, it is evident that relatively few plants are examining enough dilute samples on raw water to

produce a high enough density picture. This is especially true at times of high loading when the technician calculates coli density from a series of dilution tubes which are all positive in the highest dilution. Inasmuch as it is increasingly recognized that the character and degree of maximum loading is important, stress must be laid upon the need for obtaining reasonably accurate figures at such times. Since we must admit that few laboratories can assume new details without a compensating reduction in other demands, it appears doubly evident that reasonable simplification of coli-aerogenes identity technic is rational and much needed.

4. Out of all the discussion which has gone on for the past 10 years, it now appears that the planting of water samples into primary lactose broth tubes and (following gas production) their transplantation into secondary brilliant-green bile (2 per cent) broth produces a confirmation picture statistically so close to the old "complete" test as to justify its promulgation for all classes of waters as the standard method of determining presence and density of the coli-aerogenes group.

With these four ideas in mind, I have prepared the following general rearrangement of methods for determination of the coli-aerogenes type of organisms as they may be found in water and sewage. It has been placed in the hands of the editorial committee on *Standard Methods* as well as a number of other men interested in the subject. Naturally comments are invited.

PROPOSAL FOR REARRANGEMENT OF METHODS FOR DETERMINATION OF COLI-AEROGENES GROUP

1. The coli-aerogenes group shall be considered as including those organisms which ferment lactose with gas formation and are capable of aerobic growth on solid media. Organisms of this group are Gram-negative, non-spore forming bacilli.

2. Routine tests for this group fall into two categories.

- a. Tests for the presence of and density of the group in standard portions of the sample. Such tests, at the present time, appear best made by original plantings on one or more portions of a sample in decimal dilutions in liquid media.
- b. Tests for the relative density of organisms of the colon or aerogenes type in any standard sample portion. Such tests, expressed in relative terms only, appear best made by original plantings of standard portions of a sample in a medium which by virtue of its content of certain materials, produces colonies of both of the sought for organisms having distinct and differing appearance.

3. Tests for the density of coli-aerogenes group organisms shall involve the following required procedures for confirmation:

- a. Inoculation of standard lactose broth with a measured quantity of the sample.
- b. If fermentation with gas productions results within 24 or 48 hours transfer a loopful of the active culture into a tube of brilliant-green bile broth.
- c. If fermentation with gas production results therein within 48 hours, the presence of the colon-aerogenes group shall be considered "confirmed."
- d. The technician, at his option, may inoculate in parallel with the primary lactose broth tube, a tube of brilliant-green bile broth, methylene-blue erythrosine brom-cresol-purple broth or other modified lactose broths having similar selective action. The use of such materials shall not be related to the density picture produced by the primary lactose broth tubes, but shall be related to such ideas as to activity of pollution as the technician may have gained in his experience with water supply treatment problems.
- e. The technician may, at his option, at the same time the secondary brilliant-green bile tube is planted, transfer a portion of the lactose broth growth to a tube (slant) or plate of plain agar, Endo's agar, eosine-methylene-blue agar, methylene blue erythrosine brom-cresol-purple agar or similar solid media in order to demonstrate the ability of the organisms to grow under aerobic conditions and to indicate if desired the type of organism present in the primary broth culture.
4. In making dilution plantings, the amounts of sample selected should be such that the

largest portions will result in gas production in all or the majority of broth tubes into which they are inoculated, and such that the smallest portions will result in no gas production in all or the majority of broth tubes into which these smallest portions are inoculated. Because the numerical value of the bacterial content is largely determined by the analytical result of that dilution or dilutions of the sample intermediate between the above mentioned ones, the greater number of tube plantings should be made of this intermediate or critical portion. The number of such critical portions to be inoculated will be governed by the desired accuracy of the result (and for finished drinking waters should be not less than 5) while, the numbers of largest and smallest portions to be inoculated will be governed by the probable accuracy of the estimate of the bacterial content at the time the series of dilutions is decided upon. (This paragraph has been phrased by J. K. Hoskins of the U.S.P.H.S.)

Computation of coli-aerogenes density based upon plantings in liquid media shall be made according to the methods outlined in *Public Health Bulletin No. 1170* or later publications by them on this subject.

5. Tests for the relative density of the colon or aerogenes type shall be made by planting a sufficient quantity of the sample in a medium which becomes solid at incubator temperature and upon which the organisms of the two types grow with distinct and differing characteristics. Cyanide citrate agar, methylene-blue erythrosine brom-cresol-purple agar or brom-thymol-blue agar may be used for this purpose. Plates shall be poured in such numbers or having such density of colony growth as to produce not less than 10 colonies of the coli-aerogenes type if the relative density of each type is to be recorded.

It should be remembered that the present state of knowledge regarding the relative growth supporting powers of these solid media on the one hand, and lactose broth on the other, is not sufficient to justify the enumeration of absolute density of coli-aerogenes group organisms by the pour plate method. The decimal dilution method involving the use of primary lactose broth tubes remains the accepted method of enumerating coli-aerogenes density.

Completion of the diagnosis of the character or the organisms grown on the pour plate shall be made by the use of methods XIX-c and XX in appendix II, 7th edition--*Standard Methods*.

M. H. McCrady, F.A.P.H.A.

Chief of Laboratories, Provincial Bureau of Health, Montreal, Que.

THE following results of a recent comparison of methods for confirming lactose broth presumptives may be of interest in connection with this discussion. All routine broth tubes planted with 10 c.c. portions of water which showed gas were tested by two methods of confirmation:

Complete confirmation by Standard Methods

Gas production within 48 hr. in brilliant-green bile 2 per cent inoculated with a loopful of the presumptive lactose broth.

The majority of the waters examined were from wells and springs, many from slightly polluted surface waters; only a few were from treated or filtered supplies. Most of the published work on brilliant-green bile has been done on treated or filtered water; in consequence, our results are of interest because of the different type of samples examined.

A total of 2,200 positive presumptives obtained from 781 samples yielded the following results:

Number identical by both methods	Number positive by Standard Methods, negative by Brill.-Green Bile	Number negative by Standard Methods, positive by Brill.-Green Bile
	186	225
1,789		
81%	8%	10%

It is interesting to note that, in the course of the confirmation of the lactose broth presumptives, the examination of two colonies instead of one colony on the eosin-methylene blue plate, resulted in 160 additional complete confirmations. In consequence, the differences noted above total only a little more than twice the error resulting from limiting the examination of the agar plate to one single colony.

These results are very promising. Many similar favorable reports of the secondary brilliant-green bile method of confirmation, when employed with

waters from purification plants, have been reported by other workers. Evidently careful consideration of this procedure as an optional method of confirmation is warranted.

Before this discussion is closed, I should like to stress one point which, in my estimation, is of extreme importance in routine water control. That is the desirability of more complete knowledge of the immediate quality of our water supplies. Because of the lack of simple official bacteriological methods, sufficiently satisfactory knowledge in this regard, as revealed by the colon test, is frequently delayed. A chlorinator may falter, a forgotten cross-connection may function, but unless the resulting pollution of the supply is excessive, we are often left in ignorance of the event until a succession of doubtful results, extending over a period of days, finally convinces us that something is wrong.

Are we sufficiently cognizant of the fact that, even when employing the official five 10 c.c. volumes of sample, the lack of precision of this method is such that the occurrence of a single positive signifies a possibility, by no means negligible, of a colon organism content of over 10 per 100 c.c. instead of the 2 per 100 c.c. indicated by the result? In order to make our knowledge more complete we should so increase the frequency of sampling as to render us more than reasonably sure that our supplies are safe. The health of large populations is dependent, in large measure, upon our laboratory work and we dare neglect no effort which may enable us satisfactorily to meet this responsibility.

The present *Standard Methods*, because of the complicated confirmation required, prohibits the desired frequency of sampling. Even in the more

prosperous years this was true; at the present time many laboratories are forced either to cut the service or to employ unofficial methods.

A determined effort, on the part of this Section and other water laboratory organizations, is in order, to attempt to

devise means not only to simplify our bacteriological methods of water examination but, if possible, to make them more dependable. It may be found impossible to effect such improvement, but we can at least make a concerted and resolute effort toward this end.

R. E. NOBLE

Bureau of Laboratories, Chicago Board of Health, Chicago, Ill.

IN Chicago, the Board of Health Laboratories receive many water samples collected for investigational purposes, brought in by the Food Bureau, the Sanitary Bureau, and the Division of Water Safety Control. Often these samples develop pseudo-positive presumptive tests in the usual incubation period, somewhat less than 48 hours, or develop only suggestive (non-typical) growth on eosin-methylene blue agar plates. Many represent the possibility of acute emergency. Therefore, the Bureau Chief wants to know definitely and as soon as possible whether colon-aerogenes organisms are present, as evidence in part, for basis of action.

In order to meet this need for definite early returns, we make a direct plating in ferrocyanide-citrate agar, in parallel with the Standard Method. To illustrate the practical advantage of these direct plating results, I cite one instance which concerns a wide survey of the drinking water on the grounds of the World's Fair which caused those in authority a considerable amount of worry, because a few isolated samples from drinking stands had been found contaminated. This was during the peak of attendance, and the element of emergency was quite pronounced.

Seven samples were collected September 5 from one drinking water concession. On the morning of September 7, about 42 hours after the initial plantings, the following comparative results were recorded: All samples except 1 showed gas in lactose broth. Of

those, the direct plating results showed all but 2 samples negative for the colon-aerogenes group. At this point, as you can appreciate, the gas formation in the tubes would have accentuated the worry in the absence of any additional information such as was afforded by our direct plates. Upon completion of the standard test, requiring 5 days, 2 samples were negative by both methods; of the remaining 5 samples, 3 were negative by direct plates but positive by the standard test, with indices of 6, 6, and 10 per 100 c.c. All portions which confirmed to give these indices, except 1, showed non-typical colonies on eosin-methylene blue agar plates. The 1 showed aerogenes growth; the fourth showed only aerogenes by both methods; the fifth showed only *B. coli* by the Standard Method, while the direct plating 1 revealed both coli and aerogenes present.

The point to be made here is that the Bureau Chief was no longer interested in the 5-day results because action had already been taken on the basis of the 42-hour direct plating results. Incidentally the situation proved to be merely a local infection which was cleared up promptly, and all apprehension removed.

This is a fairly representative picture of how the two methods work in parallel. In the interpretation of the bacterial results from the hundreds of private well samples in conjunction with the corresponding sanitary surveys, examined each season in our labora-

tory, this direct plating method has proved of great help in determining whether a sample represents gross fecal pollution, surface drainage contamination, or probable infection of washers or

packing in the pumping or distribution system, and whether such infection consists of colon-aerogenes types, separately or together, or whether it is caused merely by extraneous forms.

R. S. BREED, PH.D., F.A.P.H.A.

New York State Agricultural Experiment Station, Geneva, N.Y.

THIS discussion has been very interesting to those of use who are responsible for preparing *Standard Methods for the Bacteriological Examination of Milk*. Provisional methods for making determinations of the presence of organisms of the colon group have been included in the new (6th) edition of *Standard Methods of Milk Analysis* so that any comparative study that is to be made of methods of determining the presence of organisms of the colon group in water and sewage will have a direct bearing on methods of milk examination and the studies planned should be made with this thought in mind.

As a result of papers that were presented this morning before the Laboratory Section it is evident that comparative studies should also be started

in a series of milk control laboratories with the purpose in mind of determining whether a change should be made in our standard incubation temperature from 37° C. to 32° C., introducing at the same time an agar with a composition that will grow a larger proportion of the bacteria normally present in the milk than does our present standard agar.

While this matter has no direct bearing on this discussion, I have always wondered why students of water bacteriology are content to use such unsatisfactory methods of making bacterial counts from water as are included in our present standard procedures. It seems to me that any studies on methods of counting bacteria in milk should be made so as to apply to water and sewage as well.

Ninth Conference of the International Union Against Tuberculosis

THE Ninth Conference of the International Union Against Tuberculosis will meet in Warsaw, Poland, on September 4-6, 1934, under the chairmanship of Prof. Pieztrzynski.

Delegates are expected from the 43 countries represented in the Union. An attractive program of receptions and excursions has been arranged and visits will be made to the important anti-

tuberculosis institutions of Poland.

A special party is being arranged from the United States and for those who can leave in advance a trip to Russia is scheduled that will permit delegates to arrive in Warsaw in time for the meeting. Further information may be obtained by addressing the National Tuberculosis Association, 50 West 50th Street, New York.

Studies on Acidophilus Milk*

C. N. STARK, RUTH GORDON, J. C. MAUER, L. R. CURTIS, and
J. H. SCHUBERT

Laboratory of Bacteriology, Cornell University, Ithaca, N. Y.

IN order to obtain more information upon the therapeutic value of acidophilus milk, experiments have been conducted on 124 persons over a period of 18 months, examining 2,172 samples of fecal material from these patients. An attempt has been made to establish, approximately, certain physical and biochemical properties and the bacteriological flora of human beings:

1. Who have not consumed acidophilus milk
2. Who were consuming daily 50-100 gm. of beta lactose
3. Who were consuming daily 1 quart of sweet milk containing 3 per cent of added beta lactose
4. Who were consuming acidophilus milk
5. Who have previously consumed acidophilus milk

Of the 124 patients studied, 66 were constipated or abnormal. The remaining 58 considered themselves non-constipated or normal before beginning consumption of acidophilus milk. Data obtained from these two types of persons have been studied separately in an endeavor to establish any differences in the physical and biochemical properties and the bacteriological flora of their feces. All patients on this experiment continued their regular diet, exercise, etc., in so far as it was possible. Any changes observed may, therefore more logically be assumed to have been caused by the consumption of

lactose, or milk to which lactose had been added, or acidophilus milk.

Of the 2,172 samples of fecal material examined, 734 were from 124 patients who had never consumed any acidophilus milk; 36 from 3 patients who were consuming daily 50-100 gm. of beta lactose; 113 from 12 patients consuming daily 1 qt. of sweet milk to which 3 per cent of beta lactose had been added; 1,038 from 91 patients while consuming acidophilus milk; 175 from 25 patients after their consumption of acidophilus milk, and while they were consuming sweet milk to which 3 per cent lactose had been added; and 76 from 15 patients after their consumption of acidophilus milk, and while consuming sour milk containing 3 per cent added lactose, but no acidophilus bacteria.

Laboratory tests were applied to each sample of feces to determine:

1. Number of lactobacilli
2. The number of Gram-negative, non-sporulating, gas producing colon types
3. Streptococci
4. Yeasts
5. Sporulating anaerobes
6. Sporulating aerobes
7. pH
8. Amount of indol.
9. Total weight
10. Per cent moisture

All of the persons examined were found to have lactobacilli in their intestinal tracts. The number most often found present was 1,000 per gm. of feces. Approximately 40 per cent of the samples were found to have more

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1931

than 1,000 per gm., occasional samples containing more than 1,000,000 per gm. The results of these experiments indicate that the consumption of these amounts of lactose, sweet milk to which lactose had been added, or acidophilus milk with or without additional lactose influenced little or not at all the numbers of lactobacilli normally growing in the human intestinal tract.

During the time the patients were drinking acidophilus milk, approximately 35 per cent of the samples examined contained more than 10,000,000 per gm. of the acidophilus bacteria being consumed. Approximately another 35 per cent contained from 100,000,000 to more than 1,000,000,000 of the acidophilus bacteria fed in the milk.

The types of acidophilus bacteria in the milk soon disappeared from the feces after discontinuing the consumption of acidophilus milk. Approximately all lactobacilli, of the types fed in the milk, disappeared within 2 to 6 weeks after stopping the consumption of acidophilus milk, even though patients continued to take milk containing added lactose.

The gas producing, non-sporulating colon types of bacteria were found to be present in numbers exceeding 10,000,000 per gm. in more than half of the samples tested, approximately one-fifth of the samples containing 100,000,000 to more than 1,000,000,000 of these bacteria per gm. of feces. A summary of all samples examined before acidophilus milk was consumed, while it was being taken, and after its consumption, shows little or no change in the numbers of non-sporulating, gas producing colon bacteria present. The consumption of acidophilus milk over a period of 3 months or longer tended to decrease slightly the numbers of colon bacteria. This was especially true of constipated patients.

A study of the data accumulated on the number of streptococci present in

human feces from persons who had never consumed acidophilus milk showed fully two-thirds of the samples tested contained more than 10,000,000 streptococci per gm., approximately one-fifth of the samples examined containing from 100,000,000 to more than 1,000,000,000. During the period in which the patients were drinking acidophilus milk, the data indicated a very definite tendency toward a decrease in the number of streptococci present in the fecal material. This tendency was more pronounced in the non-constipated persons.

A very small number of yeasts were found; more than half of the samples contained less than 100 per gm. Occasional specimens contained as many as 1,000,000 per gm., but the majority of the samples showing any yeasts, by the tests employed, contained only a few hundred per gm. of feces.

Approximately one-half of the samples from patients who had not had acidophilus milk contained more than 1,000,000 sporulating anaerobic bacteria per gm. of feces, occasional samples showing numbers exceeding 1,000,000,000 per gm. The consumption of acidophilus milk showed a definite tendency toward decreasing the large numbers of sporulating anaerobic bacteria. Indications were observed that the numbers of *Clostridium welchii*, or that type of anaerobic bacteria which produces a rapid and stormy fermentation in milk, decreased slightly in numbers during the consumption of acidophilus milk.

The approximate numbers of sporulating aerobic bacteria present during and after the feeding of acidophilus milk were determined. From one-third to one-half of the samples tested were found to contain less than 100 of these bacteria per gm. of fecal material. Occasional samples, however, showed very large numbers, sometimes exceeding 1,000,000,000 per gm.

Fecal material from patients consuming acidophilus milk showed a definite decrease in the amount of indol present in the feces. It is not possible, however, to say how much of this decrease in indol was due to the consumption of acidophilus bacteria. The patients who drank milk to which 3 per cent lactose had been added, but containing no acidophilus bacteria, showed a similar tendency toward a decrease in the indol content of the fecal material.

By electrometric methods, the pH has been determined on all samples of feces. The data do not indicate any change in reaction or any trend toward a change due to the consumption of lactose, milk to which lactose had been added, or acidophilus milk with or without added lactose. The average pH of human feces was found to be approximately 7.30.

The results obtained on the amount of moisture present showed the stools from persons constipated contained less moisture than stools from normal patients. The consumption of acidophilus milk caused the percentage of moisture to increase in both constipated and non-constipated persons. During the period of 4 to 6 weeks after the patients had discontinued acidophilus milk, and were consuming milk con-

taining added lactose but no acidophilus bacteria, the amount of moisture in the stools from constipated persons gradually tended to revert to its original amount. During this period the moisture content of non-constipated persons continued to remain high. The moisture content of constipated persons was about 72.0 per cent; of non-constipated persons about 74.0 per cent; of persons consuming acidophilus milk 76.0 to 77.0 per cent.

The average weight of 348 stools collected from persons who had never consumed acidophilus milk was approximately 95 gm. Of 839 stools from patients consuming acidophilus milk, the average weight increased fully 10 gm., the increase being as much as 20 gm. on stools from non-constipated persons. The data indicate at least a part of this increased evacuation to have been caused by the consumption of lactose in the milk.

Of 74 persons who finished these experiments, 43 were constipated. Twenty-nine of this number, or approximately two-thirds of those persons experiencing intestinal difficulties, were benefitted by acidophilus therapy. A majority of the non-constipated persons reported themselves in a much better physical condition while they were drinking acidophilus milk.

Vaccine Prepared from Chicken Embryo Cultures for Immunization Against Smallpox*

JULIA M. COFFEY

*Division of Laboratories and Research, New York State Department of Health,
Albany, N.Y.*

MODIFICATIONS in the method of preparing smallpox vaccine, in general, have had as their objective a bacteria-free product which would induce the maximum number of "takes" with the minimum of severe reactions. Approximately 20 years ago, the production of vaccine by the testicular method developed by Noguchi¹ was undertaken in this laboratory, but the instability and variability of the potency of this material made it unsuitable for general distribution. Recent literature contains the description of two other methods by which bacteria-free vaccines may be obtained; namely, those of Li and Rivers,^{2, 3} and of Goodpasture and his coworkers,⁴ which latter seems more complicated and to offer more opportunity for contamination than the former. The procedure of Li and Rivers consists of cultivating vaccine virus in shallow layers of a medium made by suspending in Tyrode's solution a small quantity of minced tissue from 10 day old chicken embryos.

This technic was used in preliminary experiments, begun in June, 1931, with a dermal strain of virus obtained from Rivers, to determine the effect on the potency of the virus of continued culti-

vation *in vitro*. The first lot of medium prepared was inoculated with 0.25 c.c. of a 1:20 dilution in Tyrode's solution of the sixteenth generation in the embryo medium preserved with 50 per cent glycerol. Each of the following transfers, made at 5-day intervals, was inoculated with 0.25 c.c. of undiluted and unglycerolated material from the preceding generation. The potency of the virus in each generation was determined by the cutaneous reactions induced in rabbits from 5 to 7 days after inoculation with 0.25 c.c. of various dilutions of the culture in Locke's solution.

Since, after 32 generations in the chicken embryo medium, the potency of the virus had decreased markedly, testicular passage through rabbits was resorted to. After 2 passages, a new series of cultures *in vitro* was initiated, the testicular emulsion being used as seed. Graph I summarizes these experiments. It is evident that, although the potency of vaccine virus decreases after prolonged cultivation *in vitro*, according to tests on rabbits, it may be reestablished by passage through rabbits, and that loss of potency seems to occur less rapidly after animal passage.

The glycerolated vaccine made from 5-day cultures in the embryo medium has been tested for stability at various temperatures. The tissue cultures were

* Read before the Laboratory Section of the American Public Health Association, at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

GRAPH I—Effect of cultivation in chicken embryo medium on the potency of vaccine virus

Each point represents average titer of 5 consecutive generations. Titer = highest dilution, 0.25 c.c. of which induced within 7 days a positive cutaneous reaction in rabbits.

pooled and rubbed through copper gauze and an equal volume of glycerol was added. Portions of this material were tested on rabbits after periods of 24 and 48 hours at 37° C. and of 48 hours at 3° C. in shallow layers open to the air. Twenty-five hundredths c.c. of a 1:10,000 dilution of each induced definite reactions when injected intracutaneously in rabbits. The reactions induced by the material which had been incubated at 37° C. were slightly weaker. Areas of scarified skin which had been inoculated with the undiluted vaccine of all three lots developed confluent vesicles.

Results of the storage of vaccine in small rubber-stoppered bottles at room temperature, 3° C., and -5° C., are given in Graph II, from which it is obvious that the deterioration of the material exposed to the air is much less rapid at the lower temperature. Other lots of vaccine have been stored under

a vaseline seal at 3° C. for 12 months and at -5° C. for from 13 to 20 months without apparent change in potency. The glycerolated material has been used to initiate new cultures in the chicken embryo medium after 8 months' storage at -5° C. with excellent results.

After the completion of these experiments on the effect on potency of continued cultivation *in vitro* and of storage at various temperatures, the results of which are largely confirmatory of the work of Rivers,^{3, 5} vaccines were prepared for human inoculation. One lot of glycerolated vaccine (No. 1) which had been stored under a vaseline seal for 1 year at -5° C. and had been proved by repeated sterility tests to be free from both aerobic and anaerobic bacteria, was filled in capillary tubes in approximately 0.02 c.c. amounts. This vaccine, a 1:1,000 dilution of which induced a reaction in rabbits, failed to

"take" in 4 unvaccinated children, aged 2 years, when inoculated by the multiple-puncture (10-20) method.

Another vaccine (No. 2) which had been stored for only 1 month and was of sufficient potency to react in rabbits in dilutions of 1:100,000 or 1:10,000, was filled in capillary tubes. The vaccination by the multiple-puncture (30) method of 2 children under 2 years of age with this material resulted in 1 "take." The 5 children unsuccessfully inoculated were revaccinated with vaccine No. 2 by the single-scratch method. All but 1 developed primary vaccinia. In 4 other children from 1½ to 2½ years of age, this vaccine inoculated by the single-scratch method induced 2 "takes."

The vaccination by the single-scratch method of 14 children under 2 years of age with a third vaccine similar in all respects to vaccine No. 2, resulted in 7 failures. Five of these children later developed "takes," following vaccination with calf lymph; 1 failed to react, and 1 was not reinoculated.

In order to control the technic of

vaccination by the single-scratch method, two groups of 4 children each were vaccinated with calf and tissue culture vaccines respectively. The calf vaccine induced 3 "takes"; the experimental material 2.

The reactions induced by the tissue culture vaccine were in no way remarkable. Four of the 14 who developed "takes" had temperatures of over 99° F. during the course of the vaccination. In 1 case, the temperature rose on the second day after inoculation and continued for 4 days between 105.4 and 100° F. The local reaction was not severe nor was there any glandular involvement. In 2 other cases, the temperatures ranged from 103 to 99° F. between the 6th and 12th days after vaccination. The local reaction in 1 of these children was severe and the axillary glands were palpable for several days. The fourth child developed an ear infection on the 4th day following inoculation. His temperature rose to 104.8° F. on the same day and returned to normal on the 9th day. In all cases, complete healing occurred

GRAPH II—Potency of vaccine stored in small rubber-stoppered bottles at different temperatures, without exclusion of air

in from 3 to 6 weeks, leaving a scar of less than 1 cm. in diameter.

Although the number of human vaccinations reported in this paper is insufficient to form a basis for any significant conclusions as to the efficacy of the culture vaccine, it is apparent that the method of inoculation markedly affects the percentage of "takes." Of 28 multiple insertions of unglycerolated culture vaccine on 7 children, 25 positive reactions are reported by Herzberg.⁶ Rivers⁷ has reported only 1 failure in 35 inoculations of glycerolated vaccine by scarification, while we obtained by the single-scratch and multiple-puncture methods only 14 positive reactions in 23 cases, some of which were revaccinated before "takes" resulted. It may be that the use of a more rigorous method of inoculation or a more potent vaccine can be safely resorted to with the culture material.

CONCLUSIONS

Vaccine virus, when cultivated for long periods in a medium consisting of minced chicken embryo tissue suspended in Tyrode's solution, gradually decreases in potency according to the cutaneous reactions induced in rabbits.

The potency of the culture virus can

be regained by passage through the testicles of rabbits.

Vaccines prepared from chicken embryo cultures can be stored at low temperatures for considerable periods without loss of potency if air is excluded.

Children vaccinated with culture vaccine developed characteristic primary vaccinia, but the percentage of "takes" is lower than that among children vaccinated with calf lymph, when either the multiple-puncture or single-scratch method is used.

Since the culture vaccine is both potent and stable, further study should be carried out to determine a method of preparing it for distribution so that it will equal calf lymph in efficacy.

Effect of Temperature of Incubation Upon Agar Plate Count of Milk*

CARL S. PEDERSON, PH.D., AND M. W. YALE, PH.D.

New York Agricultural Experiment Station, Geneva, N. Y.

DURING the course of studies on temperature variations in bacteriological incubators¹ marked discrepancies in colony counts from duplicate standard agar plates were noted. Lack of information on the causes for such discrepancies led to their study. It was found that slight variations in temperature from 37° C., were responsible for significant errors in colony counts.

In view of the fact that in studies of 14 different bacteriological incubators, none varied less than 2° C. during a 48 hour period even when lightly loaded while one varied in temperature as much as 11° C., it seemed desirable to study in detail the effect of temperature of incubation upon the standard agar plate count of various dairy products.

METHODS

Usually 75 duplicate agar plates were prepared from a milk sample according to the *Standard Methods* of the American Public Health Association. Either 5 or 10 of these were placed in incubators operating at approximately 21°, 25°, 30°, 32°, 35°, 37°, 39°, 45°, and 55° C. In each incubator the plates were grouped about a closed flask of water containing a thermometer. At least 5 temperature readings were taken during the 48 hour incubation

period. The average temperature reading was then assumed to be the approximate temperature of incubation of the agar plates. The colonies were counted at the end of a 48 hour incubation period ± 3 hours. From these counts the average number of colonies obtained upon the plates in each incubator was calculated.

In order to compare different samples of milk, average colony counts were calculated as percentages of the maximum average colony count. Percentages were then plotted against temperatures of incubation and a smooth curve drawn between points from which, by interpolation, the equivalent percentage for any temperature of incubation could be determined.

RESULTS

The effect of the temperature of incubation upon the plate count obtained from 78 samples of dairy products has been studied, but since they represent different types of products, they will be treated in groups.

Bottled Pasteurized Milk from Various Cities—Twenty-nine samples of bottled pasteurized milk were obtained from 25 dealers in the following large cities: Detroit, Boston, New York, Newark, N. J., Philadelphia, Rochester, and the smaller cities of Elmira, Seneca Falls, Ithaca, Watkins Glen, Maspeth, Phelps, and Geneva, located in New York State. In the majority of cases, the milk was examined within the 24 hours following pasteurization and was

* Approved by the Director of the New York Agr. Exper. Sta. for publication as *Journal Paper No. 14*. Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

representative of bottled pasteurized milk as it was delivered to the consumer. None of the samples in this series showed the presence of thermophilic bacteria when agar plates were incubated at 55° C.

In general, the curves show an increasing count as the temperature is increased up to about 32° C. (Figure 1). As the temperature is increased above this the count decreases. To be more specific, of the 29 samples, 12 apparently showed a maximum 48 hour count at 32° C., 4 at 31½°, 8 at 31°, 2 at 32½° and 1 each at 30°, 33° and 34½°. With temperatures much below 32° C., the 48 hour incubation time was too short to allow development of many colonies to a stage where they were visible to the eye.

The curves show that the maximum average colony count for all samples was obtained with an incubation temperature of approximately 32° C. Occasionally when the average 32°

count was only slightly above the 37° count, the highest counts from individual plates at 37° were higher than the lowest counts from individual plates at 32° C. Samples were more comparable at 32° C. than at any other temperature of incubation. That is, at that temperature, the least variation from the maximum count, from 85 to 100 per cent was obtained. Only the one sample showed average counts at 32° C., less than 95 per cent of the maximum count obtained.

The curves also show that the 37° C. count is, on the average, approximately only 50 per cent of the 32° C. count although great variation in this respect may be noted between the different samples. The 37° C. count ranged between 10 per cent and 89 per cent of the maximum count, thereby showing a definite lack of uniformity in the percentage of the maximum count. Furthermore, 37° C. in general, is at the steepest part of the descending

FIGURE II—Relation between temperature of incubation and colony counts obtained from 13 samples of pasteurized milk from one distributor. Standard agar plates used. Incubated for 48 hours.

curve which means that temperature variations from 37° C. are responsible for great errors.

Bottled Pasteurized Milk from a Single Source—Counts were obtained from 13 samples of pasteurized milk collected from a local distributor during a period of 18 months. The curves (Figure II) are similar to those for samples of pasteurized milk collected from a variety of sources. A temperature of 32° C. is again superior in many respects to one of 37° C. Of the 13 samples, maximum counts were obtained for 2 at 31°, 7 at 31° to 32°, 3 at 32°, and 1 at 33°. The 32° count was from 98 to 100 per cent of the maximum in all cases. On the other hand, the 37° count varied from 36 to 89 per cent of the maximum.

Bottled Pasteurized Milk Containing Thermophiles—Eight samples of pasteurized milk which were found to contain numerous thermophilic bacteria upon incubation of agar plates at 55°

C. were examined. These were obtained from dairies in New York, Philadelphia, Detroit, Boston, Rochester, and Waterloo, N. Y. If the individual curves (Figure III) are followed, it will be noted that in each case there are two peaks, the first of which occurs at about 32° C. and the second at 45° C. to 55° C. Microscopic examination of these milks revealed that many of the thermophiles did not develop colonies on plates. This is not surprising as it has been shown that thermophiles do not develop readily after the milk sample has been refrigerated 24 hours. In the case of 7 out of 8 samples, 32° counts were higher than 37° C. counts. This was evidently due to the fact that 37° C. was near the minimum temperature for the growth of the thermophilic bacteria.

Bottled Raw Milk—Counts were obtained from 8 samples of raw milk from individual producers in New York State. Seven of these producers were

FIGURE III—Relation between temperature of incubation and colony counts obtained from 8 samples of pasteurized milk containing thermophiles. Standard agar plates used. Incubated for 48 hours.

delivering to a Grade A pasteurizing plant where the standard agar plate count was used as the basis for the payment of premiums for milk with low bacterial counts. The maximum count was obtained at 32° C. for 5 samples, at 31° C. for 1, and 30° C. for 2 (Figure IV). On the average, at 37° C., about 70 per cent of the maximum

count was obtained. The 32° C. counts varied from 91 to 100 per cent of the maximum while the 37° C. counts varied from 65 to 78 per cent of the maximum count. It may again be observed that 37° C. is in the steep part of the downward curve, and that temperature variations in 37° C. incubators will result in greater errors in the

FIGURE IV—Relation between temperature of incubation and colony counts obtained from 8 samples of raw milk from individual producers. Standard agar plates used. Incubated for 48 hours.

FIGURE V—Relation between temperature of incubation and colony counts obtained from 6 samples of raw milk from distributors. Standard agar plates used. Incubated for 48 hours.

counts from milk of this type than will similar temperature variations in 32° C. incubators.

This matter is important to Grade A milk producers in New York State because in routine milk work of this nature large numbers of agar plates must be incubated at a time. This ordinarily results in greater temperature variations than in more lightly loaded incubators.

Six samples of raw milk collected from 6 small raw milk distributors produced counts of a similar nature (Figure V). It will again be noted that 32° C. incubation is superior to 37° C. The maximum counts were obtained at from 31° to 33° for 5 samples, but the 6th showed a maximum at a lower temperature, possibly about 27° C. The 32° counts varied from 88 to 100 per cent of the maximum while the 37° varied from 12 to 88 per cent.

Ice Cream Samples—Six ice cream samples representative of the pack of three small dealers and three large com-

mercial concerns were examined. It will be noted (Figure VI) that the percentages of the average maximum counts are much higher at incubation temperatures below 32° than in the case of the milk samples, indicating that the bacterial flora was composed of many organisms that grew well at low temperatures. The great variation between curves at 37° C. and the slight variation between curves at 32° C. indicate that 32° C. incubation is better than 37° C. for comparing the quality of different ice cream samples.

Cream Samples—Two samples of cream were plated, both showing curves similar to the others, the maximum count being obtained at 31°. the 37° counts being approximately 60 per cent of the maximum.

Miscellaneous and Unusual Samples—Six other samples of raw milk were tested. Three of these, 1 a sample of milk from a mastitis infected cow, showed a uniform count regardless of temperature of incubation. Average

37°	0	0	32°	0	0
38°	+ 1	— 28	33°	+ 1	— 3
39°	+ 2	— 49	34°	+ 2	— 13

Average percentage of maximum count at 37° C. = 47.7
Average percentage of maximum count at 32° C. = 98.9

counts varied from 87 to 100 per cent at temperatures ranging from 30° to 39°, with rapid drops in counts above or below these temperatures. One of these showed a high count at 37°. The results obtained from the 3 remaining samples could not be used because the plates at 30°, 32°, and 35° contained too many colonies to count accurately. From estimates, the 37° count from 1 of these was about 4 per cent of the 32° count.

DISCUSSION

The standard 37° count does not give a definite percentage of the maximum count that may be obtained from standard media. Rather a great discrepancy exists in that counts have been obtained on different samples of milk showing that the 37° C. count may be as low as 4 per cent and as high as 100 per cent of the maximum that may be obtained. Counts from pasteurized milks average about 50 per cent of the maximum count, while counts from raw milks average somewhat higher than this.

Since incubator temperatures readily vary at least 2° from the standard of 37° under normal operating conditions, it is essential that consideration be given to the percentage error in count caused by temperature variations.

With 37° C. incubation as the standard (Table I) an incubation temperature of 35° C. (2° low) yielded on the average a colony count on the 42 samples of pasteurized milk, 71 per cent too high, while an incubation temperature of 39° C. (2° high) yielded an average colony count 49 per cent too low. An incubation temperature of 36° (1° low) yielded an average colony count 33 per cent too high while an incubation temperature of 38° (1° high) yielded an average colony count 28 per cent too low. These results show that while underheating of 1° and 2° reveals more bacteria than overheating, it is responsible for greater percentage errors than overheating.

How does this compare with the errors caused by similar variations from an incubation temperature of 32° C.? If the 32° C. count is considered as the standard, an incubation temperature of 30° C. (2° low) yielded a colony count 6 per cent too low (Table I) while an incubation temperature of 34° C. (2° high) yielded a colony count 13 per cent too low. An incubation temperature of 31° C. (1° low) yielded a colony count only 1 per cent too low, while an incubation temperature of 33° C. (1° high) yielded a colony count 3 per cent too low.

TABLE II

AVERAGE PERCENTAGE ERROR CAUSED IN STANDARD AGAR PLATE COUNTS OF 14 SAMPLES OF RAW MILK BY 1° AND 2° VARIATIONS FROM INCUBATION TEMPERATURES OF 37° C. AND 32° C.

Average Percentage Error Due to Temperature Variations from

37° C.			32° C.		
Tempera- ture of Incubation	Variation in ° C.	Average Percentage Error	Tempera- ture of Incubation	Variation in ° C.	Average Percentage Error
35°	—2	+48	30°	—2	—4
36°	—1	+26	31°	—1	—1
37°	0	0	32°	0	0
38°	+1	—22	33°	+1	—2
39°	+2	—38	34°	+2	—6

Average percentage of maximum count at 37° C. = 68.0

Average percentage of maximum count at 32° C. = 98.0

The data for 14 samples of raw milk when compared in the same way show similar percentage errors (Table II). Examination of the data on 8 samples of pasteurized milk containing thermophiles also shows similar percentage errors (Table III). These, of course, are not as significant since the variation in results from individual samples (Figure III) is so great.

It is therefore evident that variations from 32° C. caused much smaller errors than did variations from 37° C.

While others ^{2, 3} have recognized the

fact that incubation temperature at or near 30° C. gives counts higher than counts obtained at 37° C., and have argued for the use of lower incubation temperatures in standard methods for this reason, it is believed that this is the first time that it has been pointed out that the use of a temperature that yields the maximum count, at the same time reduces the size of errors due to variations in the temperature of incubation. Although the temperature at which the maximum count from milk samples is obtained varies somewhat de-

TABLE III

AVERAGE PERCENTAGE ERROR CAUSED IN STANDARD AGAR PLATE COUNTS OF 8 SAMPLES OF PASTEURIZED MILK CONTAINING THERMOPHILIC BACTERIA BY 1° AND 2° VARIATIONS FROM INCUBATION TEMPERATURES OF 37° C. AND 32° C.

Average Percentage Error Due to Temperature Variations from

37° C.			32° C.		
Tempera- ture of Incubation	Variation in ° C.	Average Percentage Error	Tempera- ture of Incubation	Variation in ° C.	Average Percentage Error
35°	—2	+52	30°	—2	—13
36°	—1	+20	31°	—1	—4
37°	0	0	32°	0	0
38°	+1	—11	33°	+1	—4
39°	+2	—16	34°	+2	—13

Average percentage of maximum count at 37° C. = 44.8

Average percentage of maximum count at 32° C. = 72.8

pending upon the sample, the average is very close to 32° C. and therefore this becomes a more desirable incubation temperature than 37° C.

It is realized that a change in incubation temperature in *Standard Methods* would necessitate the installation of a second incubator in a number of laboratories. In rooms where the temperature is warmer than 32° C., it is impossible to operate satisfactorily an incubator at 32° C. without installing some cooling device.

It is also possible that a change in composition in standard agar might so affect the counts that the temperature at which the maximum count would be obtained might be somewhat higher or lower than here reported. A change of length of time of incubation might also have a similar effect.

SUMMARY

An incubation temperature of 32° C. for 48 hours instead of 37° C. is recom-

mended for standard agar plates prepared from samples of milk and ice cream.

With 48 hour incubation, higher colony counts are obtained at 32° C. than at 37° C., resulting in a truer measure of quality.

At 32° C. there is less error in counts than at 37° C. due to temperature variation in the incubator.

The percentage of the maximum counts obtained in 48 hours varies considerably at 37° C. but is quite constant at 32° C. Therefore counts obtained at the latter temperature serve as a better means of comparing the quality of different samples.

Health and Beauty

"SOMEONE had estimated that the regular customers of the 'beauty' industry in the United States number over 20,000,000 women, or 5 times as many as the total number of men enrolled under the American flag during the World War. . . . The procession passing in and out of the beauty parlors spends more than half a billion dollars a year, we are told, or more than one and a half million dollars a day. . . . If these women realized the beauty that health brings, some of the millions of dollars now spent in beauty parlors might go, with better results, for healing the big and little illnesses

that dim the eye, line the face, droop the erect figure, and play havoc generally with good looks.

"Every doctor can tell of beauty that has been brought back by restored health. Yet the big parade of women chasing beauty passes the doctor's office by, and pours a flood of gold into the purses of the beauticians. If the truth could only be implanted in woman's mind that there is no beauty like good health, the physicians would have a truly golden opportunity to improve the health and looks of the nation."—Editorial, *New York State J. M.*, Feb. 15, 1934, p. 159.

Microbiological Examination of Fresh and Frozen Fruits and Vegetables*

FRED W. TANNER, F.A.P.H.A.

Department of Bacteriology, University of Illinois, Urbana, Ill.

BACTERIOLOGICAL examination of foods has a several-fold purpose: (1) to protect the consuming public from bacteria causing food poisoning and food-borne infections; (2) to determine the relation of the indigenous microbial flora to problems of food preservation; (3) to secure information concerning the conditions under which foods have been produced and handled. These purposes are especially significant for fresh and frozen fruits and vegetables.

Despite the fact that bacteriology has been of great service in the control of certain foods, it is almost without value for routine control of others. These limitations are frequently not recognized by those not familiar with bacteriological technic. Attempts to determine the value of various methods of examination and to arrive at standard procedures are commendable. Methods quite suitable for research may not be suitable for routine control work. Time is an important factor since in control work it is essential to have results as quickly as possible.

As indicated by the title, only fresh and frozen fruits and vegetables are considered in this paper. It is proper to ascertain the actual bacteriological condition of such foods as they appear on

the market, in order to determine whether there is a need for control work.

FRESH FOODS

Fresh foods may be heavily seeded with various types of microorganisms which are picked up from the soil, dust, and agents with which they come in contact. A complete review of literature need not be attempted here. That pathogenic bacteria might be disseminated by fresh fruits, has been shown by Ehrlich,¹ Abbott,² Rommel,³ Ressel,⁴ Neumann,⁵ Clauditz,⁶ Sartory and Fillassier,⁷ and others. Sartory and Fillassier examined fruits exposed for sale on Paris fruit stands. Numerous saprophytic species were found to be present, most of which could be removed by careful washing. Garcia⁸ found *Escherichia coli* to be always present on common fruits (apples, lemons, oranges, and bananas). Such data indicate that undesirable bacteria may be present and justify health officers and state and federal inspectors in exercising vigilance to insure sanitary fresh foods. Smeall⁹ has quite recently suggested that some of the minor gastrointestinal disturbances common during the fruit eating season may be due to bacteria on fruit and not to the fruit itself.

Attempts have also been made to study the problem by determining the longevity of certain pathogenic bacteria on the surface of fruits. Ko¹⁰ was able to isolate *Eberthella typhi* for a considerable time from fruit which had

* Read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

been sprayed with pure cultures. Whether the natural fruit juices are bactericidal, seems to have had little study. Ko found that, in general, the acid juices were destructive; juices from partially ripened fruit were more germicidal than those from fully ripened fruit. Smeall⁹ reported that *Eberthella typhi* remained viable for 68 days on the surface of dates.

In general, fresh vegetables present greater sanitary problems than fresh fruits. Vegetables are raised in soil where they are subjected to greater possibilities of contamination. Wurz and Bourges¹¹ reported dissemination of pathogenic bacteria by vegetables grown in polluted soil or watered with infected water. Typhoid fever is said to increase every year in Paris¹² during the late summer months, most of it being attributed to fresh vegetables grown on sewage farms. While the original purpose of such lands was for raising hay, or for orchards and pastures, excellent crops soon stimulated their use for garden truck, much of which is eaten raw. Every precaution should be taken to insure that fresh vegetables are harvested from unpolluted soil for many of them are eaten without cooking. Creel¹³ observed no relation between the appearance of the vegetables and the presence of *Eberthella typhi*. Vegetables which seemed to be clean to the naked eye, were found to harbor the organism.

Epidemics of communicable diseases have been traced frequently to infected fresh vegetables. It is necessary, therefore, to know something of the conditions under which such foods are raised. Kurk¹⁴ examined the microbial condition of vegetables bought on the open market in Chicago. He particularly tried to find members of the colon-typhoid group, streptococci, and anaerobic bacteria. *Escherichia coli* was found on 22 of 29 samples of watercress, celery, and lettuce. James¹⁵

more recently studied fresh head lettuce and reported many more bacteria on the exterior of the head than in the interior. His work again showed the value of controlled conditions of storage and handling.

Just how much significance should be given to the presence of lactose-fermenting bacteria on the foods under discussion is open to argument. No information seems to be available on which to base an opinion. It is very doubtful whether they may serve as indicators of pollution of fresh foods in the same manner as they do of water.

Murillo¹⁶ incorporated pathogenic bacteria in garden soil by spraying the soil and food products grown thereon. Virulent organisms were found after 36 days in soil and after 55 days in sterile sand. Such data indicate appreciable longevity in soil. Melick¹⁷ found that longevity of *Eberthella typhi* in soil depended on the source and strain, the time varying between 29 and 58 days. Under natural conditions radishes were infected after periods of 28, 35, and 37 days. Garden soil inoculated with typhoid excreta yielded viable *Eberthella typhi* for 41, 34, and 35 days in three experiments. Melick was forced to the conclusion that fresh vegetables raised on polluted soil may be unsafe. Furthermore, the ordinary methods of preparation for the table might not render them safe.

These conclusions of actual experiments seem to be borne out by epidemiological experience. Wary¹⁸ reported an epidemic of typhoid fever in a London suburb attributed to watercress grown in beds fertilized with sewage. Another outbreak of 18 cases of typhoid fever traced to watercress sandwiches was reported from Philadelphia.¹⁹ Pixley²⁰ attributed 2 cases of typhoid fever to uncooked rhubarb. Mores²¹ believed that 49 cases of typhoid fever in an insane hospital had been caused by eating celery which had

been irrigated with sewage. Since it is known that some of our pathogenic microorganisms are quite hardy, they may be expected to survive during the commercial age of fresh foods.

Bacteria apparently do not penetrate the interior of sound fruits and vegetables. Mills, Bartlett and Kessel²² made such observations with vegetables using bacteria and particles of carbon. They adhere to the surface and may be removed by the procedures used in preparing them for the table. That these procedures may not always be reliable has been suggested by Melick.¹⁷ It is safer to prevent contamination than to rely on procedures in the kitchen to avoid infection. The superimposition of careful washing on fresh foods raised under satisfactory conditions, gives foods which harbor minimum amounts of foreign matter, including microorganisms. It has been pointed out above that vegetables which appear to be clean, may harbor pathogenic bacteria.

FROZEN FOODS

Frozen or frosted foods have assumed an important place on the American market. While this method of preservation has been used for decades, only during the last one, has it been extended to a wide variety of foods. Public health aspects of frozen foods were discussed by Fellers in 1931. At that time, there were few reports of experimental work in the literature and not much was known about the microbiological condition of such foods, and some of the foods now being frozen were not so preserved when Fellers prepared his paper. Since then, results of several extensive investigations have been reported and some of the conclusions which Fellers had to reach by analogy are now supported by experimental work. The discussion by Fellers dealt adequately with some of the general health problems, such as raw materials,

effect on nutritive values, etc. It is my intention to consider some of the newer findings. It should be stated that this is done with no prejudice against such foods. They are probably as safe as fresh foods, if properly handled and kept frozen until used. Frozen foods must endure the same analysis that foods preserved by other methods have in the past. If they are considered to be perishable and perhaps more susceptible to attack by microorganisms than are fresh foods, and are handled accordingly, they will be satisfactory foods.

Several different positions have been assumed by those engaged or interested in the development of the frozen food industry. One of them is that little attention need be given to the sanitary features because to date they have not caused infections or intoxications. Those who assume this position believe that harm is done the industry by such discussions. Such a position is untenable and violates the simplest and most fundamental laws of epidemiology. Application of such logic to the entire field of public health would lead to chaos, and discredit the public health officer. Dr. Hurty's homely poem on page 796 of the August, 1933, *JOURNAL*, "The Fence or the Ambulance," aptly expresses the situation. In this case it is better to erect fences and keep them in repair than to neglect them and have to call the ambulance. It is better to prevent trouble than to cope with it after it has appeared. The fence in this case is so easy to construct—simply sound raw materials, properly and completely frozen, and kept frozen until used by the consumer. The frozen food industry must decide whether it is willing to assume the losses which might result from improper handling of frozen food. The ripe olive industry was ruined for a number of years after the outbreaks of botulism which were traced to it. Even today, about 15 years after

the spectacular Canton, Ohio, outbreak, the ripe olive is viewed with suspicion by some laymen. Nothing is to be gained by refusing to face these hazards. On the other hand, a finer and safer food will be available if they are faced and everything done to prevent spoilage.

There has been a tendency in some quarters to compare frozen or frosted foods to other preserved foods without considering the differences which obtain. Other preserved foods may have received special treatment to destroy bacteria or repress their development. The situation with respect to frozen foods is much different. Even after storage for some time in the frozen state, they contain innumerable microorganisms in some cases, and are subject to fairly rapid spoilage after thawing. Frozen foods, like fresh foods, are perishable and must be stored under proper conditions. Here defects in quality of frozen foods may occur. Deterioration and possibility of causing food poisoning, remote as they may seem, are possible in any food in which there is a varied flora.

Freezing does not destroy microorganisms. A review of the literature of the effect of freezing on microorganisms prepared by Wallace and Tanner appears in the October and December, 1933, issues of *The Fruit Products Journal* and *American Vinegar Industry*. This survey shows beyond reasonable doubt that, while freezing does materially reduce the number of viable bacteria in some cases, it by no means destroys them. Among those which remain, may be microorganisms of considerable significance. Prescott, Bates, and Highlands,²³ and Fellers²⁴ reported appreciable numbers of viable bacteria in various frozen foods. Geer, Murray, and Smith²⁵ have recently reported satisfactory reductions in the bacterial content of Hamburg steak after freezing and storage. In the author's laboratory extensive investiga-

tions have been under way for several years on the microbiology of frozen foods, including the analysis of over 2,000 cans and cartons of frozen fruits and vegetables packed under commercial conditions. Reports on this work will shortly be published.²⁷ It seems sufficient here to report only some of the general conclusions reached. The original microbial content of the frozen foods seemed to depend largely on the condition of the raw materials. When over-ripe, blemished, raw materials were used, the content of microorganisms was high; when sound raw materials were used, the content was low. There were some instances where a container from a low count pack, contained many more microorganisms than the others. This was probably due to the presence of small amounts of decomposed food. One bad berry, for instance, might seed an entire pack or container. A fairly high content of microorganisms apparently has little influence on quality as long as the food is frozen solid, for there is no satisfactory evidence that bacteria grow under such conditions.

Freezing caused a steady decrease in the number of viable bacteria. After a year's storage, viable bacteria had decreased about 90 per cent. The number of viable forms seemed to reach a basic minimum from which it decreases very slowly. Apparently those forms which are unable to tolerate the conditions in frozen foods die out rapidly during the early period of storage.

To study the effect of freezing on the organisms themselves under conditions as nearly like those obtaining in foods, Wallace and Tanner²⁶ froze 16 different pure cultures of microorganisms, including yeasts, molds and bacteria in 16 different menstrua-nutrient broth with 5 different hydrogen ion concentrations, 3 different concentrations of salt and sugar, and in 2 fruit juices. The suspensions in ampoules were stored at

—23.3° C. (—10° F.), and counts of viable cells made at monthly intervals. In all cases there was a rapid drop in numbers during the early periods of storage. Spore forming bacteria were more resistant. After the 8th month the number of viable cells dropped very slowly. These ampoules have now been in storage for almost 3 years and still show many viable bacteria.

In order to determine whether very low temperatures might not be more destructive, bacterial suspensions were stored at —15° C. (3.2° F.), —40° C. (—40° F.) and —80° C. (—112° F.). The differences due to these temperatures were not pronounced. In fact even the lowest temperature employed, —80° C., did not seem to cause much more rapid or greater destruction than the higher ones.

It should be pointed out that the results of freezing on microorganisms, expressed in percentage reduction of viable forms may be meaningless. The important problem is the number of viable forms remaining. The fallacy of interpreting too much into percentage reductions is well illustrated by Table III in a paper by Geer, Murray, and Smith²⁵ on the bacterial content of frosted Hamburg steak. Two samples were reported as having 1,200,000 bacteria per gm. after freezing and storage. One showed a 57.1 per cent reduction, the other a 40 per cent. A 99 per cent reduction in viable microorganisms might leave many bacteria in the food.

The types of spoilage caused by microorganisms in thawed frozen foods are not unlike those in fresh foods. Whether thawed foods are more susceptible to spoilage has not been adequately studied. Berry²⁷ reported that yeasts were largely destroyed in frozen fruits and that when the cans were stored at room temperature, only a few swelled. Wallace and Tanner²⁸ found that frozen fruits packed in tin

swelled and in many cases burst the cans. Yeasts are quite resistant to freezing, as shown by Tanner and Williamson.²⁸ Observations made in the author's laboratory during the past 3 years do not confirm Berry's observations. Yeasts have been so abundant in some thawed frozen fruits that they burst the containers.

The fact that frozen foods do not receive treatment which will free them of microorganisms makes it necessary to give more attention to raw materials and conditions under which they are prepared than is the case with certain other preserved foods. Attention should be given to quality of the water supply and the health of those engaged in the preparation of such foods. A carrier would be a menace. Sufficient attention is apparently given these matters in the frozen meat and fish industries, but this may not always be the case in the frozen fruit and vegetable industry. Concentration of hundreds of fruit pickers from different sections of the country in camps during cherry picking time might introduce hazards which would be of no significance in other food industries. To secure information on the possible dissemination of such diseases as typhoid, and paratyphoid fevers by frozen fruits, fresh cherries and cherry juice in tin cans were inoculated with *Eberthella typhi*, *Escherichia coli*, *Salmonella aertrycke*, *Salmonella schottmülleri* and *Proteus vulgaris*. The cans were closed, tipped under 26 inches of vacuum, their exteriors disinfected, and stored at —17.8° C. (0° F.) and —40° C. (—40° F.). Uninoculated controls were stored under the same conditions. The results of these experiments were reported by Wallace and Park.²⁹ In the cherry juice alone, the organisms did not survive longer than 4 weeks. In frozen cherries the survival period was from 2 to 3 months. Such data justify attention to sanitary

quality of water and medical inspection of employees, for cherries might be used promptly after freezing. Heavier inoculation with more cold resistant strains than those used might tend to greater longevity.

The other problem has to do with the presence and behavior of toxicogenic anaerobes under the conditions which obtain in frozen foods. Some of those engaged in the frozen food industry have stated that it was hard to see that there was the slightest danger from the consumption of thawed frozen fruits, even under the most careless handling. It has been stated that it was common practice to allow frozen fruits to remain on counters during the day and later return them to an ordinary icebox at night, and further, that under these conditions, a large number of the cartons must have begun to ferment prior to their sale. Such careless methods of handling a perishable food should not be permitted, as they would greatly affect the quality and introduce hazards of food poisoning which may easily be avoided by proper handling. To hold that there is no danger is a questionable attitude. It probably originates from experiments with canned foods. It is generally assumed that a food more acid than pH 4.5 is free from botulism hazard. The growth of other organisms might interfere with the protective action of foods with pH 4.5, as has been shown to be the case.

Development of sufficient toxin to kill guinea pigs in a few of the fruits has been explained by concomitant development of other organisms, especially molds, making it possible for *Clostridium botulinum* to grow. Several reports confirm this explanation. Chief among them are those of Meyer and Gunnison,²⁰ and Stone.²¹ The former reported an outbreak of botulism caused by Bartlett pears the pH of which was 3.86. Development of toxin in Bartlett pear syrup was made possible by

concomitant development of a yeast and a member of the lactic acid group. This spoilage so altered the pH of the pear syrup that *Cl. botulinum* was able to grow. Stone reported an outbreak of botulism caused by persimmons, the pH of which was 5.6. Wallace and Park observed toxin formation when a yeast and acid producing bacterium were growing in the medium.

The wide distribution of *Cl. botulinum* in the soil of the areas where fruits and vegetables are frozen on a large scale is an important factor. The organism is also known to be present in the soil of practically all states as evidenced by outbreaks of botulism and examination of soil samples.

In some quarters it has been argued that packing of frozen foods in paper cartons might eliminate the danger of botulism. It was suggested that air would enter such packages and prevent development of anaerobic bacteria. The fallacy in such an argument is apparent to bacteriologists. Anaerobic conditions could easily be present in a food mass exposed to the open air. The fact that a package is not hermetically sealed is no indication that anaerobic conditions might not exist.

Effect of Freezing on Botulinum Spores—It is generally accepted that freezing does not sterilize a suspension of bacteria. The spores of *Cl. botulinum* have also been shown to be resistant to freezing. They are viable, therefore, and appear in the thawed frozen foods to compete with the other bacteria which have survived the cold. The subject has been studied in several laboratories with somewhat discrepant results. Berry²⁷ considers the possibility of botulism from thawed frozen foods to be very slight. His arguments are apparently that the foods would have taken on such appearances of decomposition that they would not be eaten, and that frozen foods are usually cooked before eating. These are as-

sumptions which do not seem to be supported by facts. As far as the first one is concerned, experience with botulism from canned foods has been just the reverse. Geiger, Dickson, and Meyer³² discussed this question in *The Epidemiology of Botulism*. They reported that in many outbreaks the spoilage of the preserved product was so striking as to attract the attention of the person opening the can; yet the foods were served. With regard to cooking of frozen pack vegetables, this may be the rule, but it is conceivable that they might be used uncooked.

Results of several investigations have been published to show that the spores of *Cl. botulinum* are not destroyed by freezing and storage in the frozen condition for rather long periods. Wallace and Park³³ observed viable spores after a year at -16°C . (3.2°F .). James made the same observation.

Effect of Freezing on Toxin of Cl. botulinum—The toxin of *Cl. botulinum* is not destroyed by freezing. Wallace and Park reported potent toxin after 1 year's storage at -16°C . (3.2°F .). James reported that freezing and defrosting 15 times did not reduce the strength of toxin.

Development of Cl. botulinum in Thawed Frozen Foods—Having shown that freezing does not destroy *Cl. botulinum* or its toxin, the next problem is to determine the behavior of the anaerobe in thawed frozen fruits and vegetables. To be safe and of high quality, frozen foods should be kept frozen until used. This is not done by all who are merchandising these products. Several years ago frozen fruits were exposed for sale on the counter in Chicago drug stores. As stated, we have the word of one engaged in the frozen food industry that the cartons are frequently not kept frozen during their sojourn in the retailer's establishment. Berry's experience in the Northwest is somewhat dif-

ferent from that in other sections. Of 20 cans of blanched peas and 10 cans of unblanched string beans inoculated with *Cl. botulinum* spores 15 to 18 months previously, none proved toxic either on thawing or on standing at room temperature for from 3 days to 3 weeks.

This has not been the experience in our laboratory as reported by Wallace and Park. It has been demonstrated in our laboratories that occasionally *Cl. botulinum* may develop in thawed frozen foods and produce its toxin. Vegetables are especially susceptible whether packed in glass or tin containers.

The results of these investigations correlate well with those reported by Straka and James.³⁵ They reported the presence of Types A and B of *Cl. botulinum* in inoculated frozen peas packed in various types of containers; showed that freezing did not destroy *Cl. botulinum*; and that frozen vegetables (peas) which contain it may become toxic after thawing. Berry stated that there is practically no danger from frozen foods.* James has shown that the toxin is not materially reduced in potency.

Having discussed the microbial condition of fresh and frozen foods, just how far may bacteriological technic be used in their control? It is difficult to see a place for the bacteriologist here, much as the food bacteriologist might wish it. It would be impossible to examine bacteriologically all shipments of such products. Negative results would be meaningless with some of our present

* Since the preparation of this paper, Berry (*J. Bact.*, 26:459, 1933) published a report of experimental work in which he demonstrated survival, for at least 2 years, of lactic acid bacteria in frozen peas. Persistence of these organisms was believed to be of public health significance in that they might exert an antagonistic influence on food poisoning bacteria. Frozen foods are not sterile and organisms which favor bacteria of the food poisoning group might be present as well as those which have been found to inhibit them.

methods. Much more may be done by careful inspection of conditions under which such foods are produced and handled. This is becoming of greater importance for fresh foods shipped into this country that may not be raised under sanitary conditions, and it is apparent that bacteriological methods may not be used for control.

Certain other foods are in about the same situation. The Bureau of Animal Industry does not examine the flesh of all hog carcasses for *Trichinella spiralis*, because it would be too expensive, if not impossible. In place of this it prescribes conditions under which the meat shall be handled to rid it of the parasite. A similar attitude must be taken toward the foods discussed in this paper.

Bundesen³⁶ reached the same conclusion in 1925 after weighing the evidence gathered in an epidemiological investigation of typhoid fever in Chicago. He stated that bacteriological examination of fruits and vegetables had not proved of any value. In the majority of instances, *Escherichia coli* was found, but it was impossible to determine its origin—whether it was of human origin or derived from the soil. In 1 case high colon counts of a shipment of lettuce were traced to ice used for packing.

The Detection of Carriers Among Food Handlers in Connecticut*

D. EVELYN WEST, EARLE K. BORMAN, AND FRIEND LEE MICKLE

*Chief Microbiologist, Assistant Director, and Director, Bureau of Laboratories,
Connecticut State Department of Health, Hartford, Conn.*

THE idea of subjecting certain groups of food handlers in Connecticut to physical and laboratory examinations took definite shape in 1927, shortly after an extensive outbreak¹ of septic sore throat among consumers of milk from a dairy producing a grade of milk designated in Connecticut as "certified." Since that time statistics have accumulated on 91,257 examinations of milk-handler specimens over a period of 77 months. Certainly sufficient data have been amassed on nearly 100,000 examinations in over 6 years to justify an analysis and to render possible an impartial evaluation of the laboratory results.

This study is not concerned with the physical examinations which are made by physicians employed by the producers. Our main purposes in this discussion are to outline Connecticut requirements for food handlers, to describe the methods used in the Bureau of Laboratories of the State Department of Health and to demonstrate by our experiences the general usefulness, importance, and relatively low cost of routine laboratory examinations of specimens from food handlers when conducted in a central laboratory doing a large volume of work.

DEFINITION OF TERMS

For a clear understanding of this paper certain terms must be defined. The term "food handler" will be used in its broadest sense to include all persons engaged in the production and handling of food until prepared for the ultimate consumer. The terms "milk handler" and "oyster handler" will be used to differentiate between particular groups of food handlers. The term "carrier" will be used broadly to include all persons harboring organisms capable of causing diseases spread by food, regardless of the permanence of the carrier state. Particular attention will be paid to carriers of certain diseases: diphtheria, scarlet fever, septic sore throat, tuberculosis, typhoid and paratyphoid fevers, and to milk as a potential disease vector.

Of the 3 grades of milk to which we shall refer, only one, "pasteurized," is self-descriptive. The other two, "certified" and "grade-A raw," are defined² in regulations of the Connecticut Milk Regulation Board, an official state body. The term, "certified," in Connecticut, does not indicate milk produced under the requirements of a medical milk commission but is defined as milk having a standard plate count of not more than 10,000 bacterial colonies per ml. and produced from tuberculin-tested cows in a dairy approved by the Connecticut Milk Regulation Board as fulfilling exacting requirements in regard to physical equip-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

ment, handling methods and health of handlers and cows. Grade-A raw milk in Connecticut is produced from tuberculin-tested cows under specifications less stringent than those for "certified" milk. It must have a standard plate count of not over 75,000 bacterial colonies per ml. with an average standard plate count of not more than 40,000 bacterial colonies per ml. for 3 successive samples. The ordinary grade of milk consumed raw by a large percentage of the population will be referred to in this discussion as "ungraded raw milk."

CONNECTICUT REQUIREMENTS

The rules specified in the Sanitary Code³ for release of cases from quarantine and for release of carriers apply to food handlers as well as to other individuals. No food handler may return to work after an attack of a communicable disease until the requirements for release from quarantine or isolation have been fulfilled.

Economic factors operate to make it imperative for health authorities to select certain key groups of food handlers for periodic laboratory examination. The primary aim in making this selection should be to protect the largest possible number of persons to the greatest possible extent from food-borne diseases spread by carriers who handle foods not susceptible to adequate supervision by other methods. Obviously, certain foods serve as disseminators of disease more often than others. Milk is a classical example. Being a liquid, it soon becomes completely invaded by any contaminating microorganisms introduced in the handling process. Furthermore, it serves as an admirable medium for the propagation of bacterial life. Its consumption is more general than any other single food and it is ordinarily ingested by all age groups without any treatment after delivery.

Reports of results of examining large numbers of specimens from food handlers are scarce in the literature. Osborn and Beckler⁴ in a survey of typhoid carriers among food handlers in Massachusetts listed 21 milk handlers who had caused 426 cases, an average of 20.3 cases per carrier. Twenty carriers among other types of food handlers caused 56 known cases, an average of only 2.7 cases per carrier. These other types of food handlers were not especially varied but included cooks, maids, housewives, nurses, and icemen. The highest case-to-carrier ratio, 7.3, among these sub-groups was for cooks. From these considerations it is evident that handlers of milk, and other foods presenting hazards nearly as great, are logical selections for laboratory control work.

The only classes of food handlers subjected to special requirements in Connecticut are oyster handlers and handlers of certified, grade-A raw and pasteurized milk. The Sanitary Code requires⁵ that each person engaged in "opening, handling or packing shucked oysters" must be examined annually to determine the absence of organisms of typhoid and paratyphoid fevers in a stool and a urine specimen before he can secure a certificate from the State Department of Health permitting him to obtain employment. Further laboratory examinations must be made after any suspected attack of typhoid fever.

The Connecticut Milk Regulation Board requires the making of laboratory tests of body discharges of all handlers of certified and grade-A raw milk before beginning employment to determine the absence of the organisms of typhoid fever, paratyphoid fever, tuberculosis, diphtheria or streptococcus sore throat. Handlers of certified milk must be reexamined monthly with the inclusion of laboratory tests. These regulations have been supplemented by an executive order of the State Dairy and

Food Commissioner, effective July 1, 1931, requiring additional laboratory tests on handlers of grade-A raw milk at least once every 6 months and laboratory tests on all handlers of milk in pasteurization plants at least once a year.

SYNOPSIS OF LABORATORY METHODS

In all instances the State Department of Health has been given power to designate the laboratory tests necessary. At present these tests consist of the following examinations: Throat and nose swabbings for *Corynebacterium diphtheriae* and hemolytic streptococci; sputum for *Mycobacterium tuberculosis*; feces and urine specimens for the organisms of typhoid and paratyphoid fevers; and blood for agglutinins for typhoid and paratyphoid organisms. The blood tests are required only at the time of the first examination but in actual practice most examining physicians submit specimens for agglutination tests at every examination, except on handlers of certified milk, in which case Widal tests are requested on the average of once a year. Specimens ordinarily reach the Laboratories within 24 hours after collection.

Diphtheria—Four cultures on Loeffler's medium are examined routinely. Two of these cultures are from nose and throat swabbings respectively, which have been planted by the physician; the other 2 are planted in the laboratory, 1 from the nose and 1 from the throat swab. A microscopical examination, using Kinyoun's stain, is made after overnight incubation.

Diphtheria Virulence Test—When a nose or throat culture is found to contain organisms morphologically resembling *Corynebacterium diphtheriae*, an intradermal virulence test is made, using the guinea pig as test animal. Tests are made with a suspension of whole culture in salt solution and the appearance of a distinct, typical, necrotic area

is used as the criterion for a positive test.

Hemolytic Streptococci—As the most expedient procedure available for routinely complying with the requirements of the Milk Regulation Board for determining "by laboratory tests" that a milk handler "does not harbor the germs of streptococcus sore throat," swabbings received from the nose and throat of each person are streaked on blood-agar plates prepared from whole, defibrinated sheep blood. Only organisms that give the true beta type of hemolysis and show typical chain-formation microscopically are considered positive; all others are disregarded. Enrichment methods for the isolation of hemolytic streptococci are not included in this routine examination since these methods are too time-consuming for our present personnel to handle. Statements ^{6, 7, 8} occur in the literature that hemolytic streptococci, when recovered in practically pure culture from the throat or nose, have diagnostic significance. Public health laboratories have somewhat generally made use of this procedure routinely. The presence of streptococci giving a true beta type of hemolysis in the throat or nose of a milk handler is considered sufficient reason for removing him from contact with a milk supply until negative tests are obtained without making biochemical, serological, or further morphological studies. Moreover, an attempt to differentiate routinely between various species, groups or strains of beta hemolytic streptococci would be an unnecessarily costly refinement in the light of our present knowledge unless undertaken as a research problem. From an epidemiological viewpoint the effect of this procedure is to give the public the benefit of the doubt as to the relationship of these organisms to scarlet fever and septic sore throat.

Tuberculosis—Sputa from milk handlers are concentrated and smears of the

TABLE I
NUMBER OF VARIOUS KINDS OF LABORATORY EXAMINATIONS ON MILK HANDLER SPECIMENS AND NUMBER OF POSITIVE EXAMINATIONS ANNUALLY, APRIL, 1927, TO AUGUST, 1933, INCLUSIVE

sediment stained by the Ziehl-Neelsen technic with subsequent microscopical examination.

Feces and Urine for Enteric Organisms—Specimens of feces are collected in vials containing a 30 per cent solution of glycerol in 0.6 per cent salt solution. Urine specimens are collected in clean, sterile vials. Organisms are isolated by streaking the specimens on brilliant-green agar and eosin-methylene-blue agar plates in a manner designed to give well separated colonies. Examinations for typhoid and paratyphoid organisms are routinely reported whether positive or negative. Dysentery and food-poisoning organisms are reported only when found. All suspected organisms are subjected to thorough morphological, biochemical, and serological tests before a report is made.

Widal Tests—Either macroscopic or microscopic Widal tests are made according to the amount of blood received for the test. In either case serial dilutions of the serum are made. Living suspensions of 24-hour agar-slant cultures are used as antigen in the macroscopic tests to assure the presence of both H and O agglutinogens. A living 15- to 18-hour broth culture is used as antigen in the microscopic tests. After mixing the diluted serum with the antigen, macroscopic tests are incubated for 3 hours at 55° C. and subsequently overnight in the refrigerator. Hanging-drop preparations for microscopic tests are incubated for 30 minutes at 37° C. before reading. Tests are made for typhoid, paratyphoid A and paratyphoid B agglutinins.

LABORATORY FINDINGS ON MILK HANDLERS

From April, 1927, to August, 1933, inclusive, a total of 91,257 specimens were examined from handlers of certified, grade-A raw and pasteurized milk. Table I shows the numbers of the

various types of examinations and the positive examinations, annually. The total of 338 positive results would be definitely misleading if not subjected to analysis and discussion. The number of positive Widal (agglutination) tests for typhoid, paratyphoid A and paratyphoid B may be dismissed at once with the statement that a positive result has never in our experience led to the subsequent detection of a carrier among this group of milk handlers. Although 6 carriers of typhoid and paratyphoid organisms have been detected in the same period of time, 4 of them gave negative Widal tests, and no Widal specimens were submitted on the other 2.

The actual number of individual carriers of organisms of milk-borne diseases detected annually is shown in Table II. Under the heading "Diphtheria" only virulent cultures are listed, representing just the "carrier" fraction of 183 positive examinations for *Corynebacterium diphtheriae* on 140 individuals. One of these cultures (1932) was not examined for virulence because, shortly after the examination was reported, it was found to be from a clinical case.

The net result of 91,257 examinations in 77 months has been to remove 71 persons, potential foci of infection, from active participation in milk handling, either permanently or until cessation of the carrier state. These individuals have included 8 carriers of virulent diphtheria organisms, 50 of beta hemolytic streptococci, 7 of tubercle bacilli, 4 of typhoid organisms and 2 of paratyphoid B bacilli. To the best of our knowledge, none of these was detected otherwise than by laboratory tests.

LABORATORY EXAMINATIONS ON OTHER FOOD HANDLERS

In Table III are presented laboratory examinations on persons known to

be food handlers (exclusive of handlers of certified, grade-A raw and pasteurized milk) extending from January, 1931, through August, 1933. The 11 individuals giving positive feces or urine specimens for typhoid organisms were all carriers, not cases, and each had been implicated as the infecting agent either in 1 or in a very few cases of typhoid fever. Thus in less than 3 years 11 carriers have been located on investigation of sporadic cases of typhoid, a fact which more than ever indicates the important rôle of the carrier in sporadic typhoid fever. Two of the 3 positive examinations for bacillary dysentery were from a single carrier who had caused a small outbreak of dysentery in an educational institution⁹; no history was obtained on the other positive examination.

Of the total of 3,176 examinations recorded in Table III, 1,869, or more than half, have been made on feces and urine specimens from oyster handlers in

fulfillment of requirements of the Sanitary Code of Connecticut. None of these were positive. However, they represent a very small group of food handlers, as not more than 125 individual oyster handlers have been examined in any one year. Although this group is small, the detection of a typhoid carrier within the group would be of importance not only to the State of Connecticut but to any community into which shucked oysters are shipped so that the small expense involved certainly seems justified. Since the beginning of 1931 the cost has never exceeded \$750 per annum on the basis of cost data which will be presented later. It should be noted here that 6 carriers had been detected¹⁰ among oyster handlers prior to the examinations recorded in Table III. One paratyphoid A and 4 paratyphoid B carriers were found in 1925 and a typhoid carrier was discovered in 1926.

The other individuals giving the

positive tests shown in Table III were mostly clinical cases. Nevertheless, the finding of tubercle bacilli in the sputa of 14 individuals in this group has given the local health authorities definite grounds for removing these persons from contact with food to be consumed by others.

COST OF LABORATORY WORK ON MILK HANDLERS

The best figure available for estimation of the total cost of making milk-handler examinations is the average cost per annum of an examination in the entire Bureau of Laboratories, translated from a fiscal to a calendar year basis. Such records have been carefully compiled and discussed in the annual reports of the Bureau¹¹ for several years. They apply only to this particular laboratory over the period specified. Because some types of examinations included in the work of our Laboratories are much more time-consuming than are most of the milk-handler tests, they naturally tend to make the "average cost per examination" figure somewhat greater than it would be if based on milk-handler tests alone. Examples are the complicated series of tests necessary in the sanitary chemical examination of a water or the classification of an unusual pathogen. Therefore, the authors maintain that the cost of milk-handler examinations as estimated on this basis is considerably higher than the actual cost has been so that any error is definitely on the side of conservatism.

Unit cost figures obtained in the manner just described are the basis for Table IV which shows the annual cost of laboratory examinations on milk handlers, and another significant figure for each year—the cost of detecting each carrier found in this group. The unit cost of locating each one of the 71 carriers from 91,257 laboratory ex-

aminations has been \$677, or a total expenditure of \$48,048 in 77 months.

The estimated population of Connecticut,¹² as of July 1, 1932, was 1,656,572. The cost for laboratory work on milk handlers given in the table for that year was \$10,858. A short calculation gives for these milk-handler examinations in 1932 a per-capita cost of approximately 2/3 cent.

The number of quarts of the various grades of milk produced daily in Connecticut according to statistics gathered by the State Dairy and Food Commissioner for one day in May of this year are as follows: certified 9,234; grade-A raw 22,249; pasteurized 415,000; and ungraded raw 324,747. This gives a total of 771,230 quarts of milk produced daily. These figures do not take into account probably 18,000 quarts of milk produced daily outside of the state but bottled in Connecticut or perhaps 65,000 quarts of milk produced in Connecticut and bottled after shipment outside of the state. It was impossible to secure figures on the amount of milk produced in Connecticut not used as fluid milk. Of the total milk supply, therefore, certified represents 1.2 per cent; grade-A raw, 2.9 per cent; pasteurized, 53.7 per cent; ungraded raw, 42.2 per cent. Assuming the per capita consumption of all grades of milk to be the same and the consumption to be evenly distributed among all persons in the state, these figures will then serve equally well as estimates of the percentages of the total population consuming the various grades of milk. The population of Connecticut, estimated¹³ as of July, 1933, was 1,678,647. Therefore, the probable number of consumers of the different grades of milk in Connecticut is as follows: certified, 20,144; grade-A raw, 48,681; pasteurized, 901,433; ungraded raw, 708,389.

Under existing requirements, there-

fore, 970,258 persons—only 57.8 per cent of the total population of the state—are benefitting from the protection afforded by the routine laboratory examinations now being made periodically on milk handlers. On the basis of the estimated cost of milk-handler examinations during the first 8 months of 1933, the cost for the entire year will not exceed \$20,000 and will probably be much less. These figures indicate the state is now spending less than 2 cents per annum on each individual consumer of certified, grade-A raw and pasteurized milk to protect him from milk-borne diseases spread by carriers who may be detected by laboratory examinations. The remainder of the population, 42.2 per cent, do not as yet have the benefit of these services until after an outbreak of milk-borne disease has occurred and been recognized as such. That the ungraded raw milk they drink is a public health hazard

is demonstrated by a number of outbreaks of milk-borne disease, traceable to it, occurring during the 77 months covered by this study. It is true that the producers of this type of milk include small farmers who milk only 1 or a few cows each day. The feasibility of extending milk-handler control work to every 1-cow dairy might be questioned but it could be extended to all dairies where the volume of milk sold would be sufficient to constitute a public health hazard without increasing the cost per examination over that for handlers of the grades of milk now examined.

On the basis of the above figures, the expenditure for these milk-handler tests for 1933 will be less than 7 cents for each 1,000 quarts of milk produced in the entire state. The average amount expended per 1,000 quarts of certified, grade-A raw and pasteurized milk will be less than 12 cents.

Certified	116	12	\$5.625*	\$7,830	\$67.50	3,370.4	232.	40
Grade-A Raw	301	2	7.00	4,214	14.00	8,121.2	51.	10
Pasteurized	1,115	1	7.00	7,805	7.00	151,475.2	5.2	1

* This figure takes into consideration the fact that Widal tests are requested by the physician on handlers of certified milk on an average of only once each year.

FREQUENCY OF MILK-HANDLER EXAMINATIONS

At present handlers of certified milk in Connecticut are examined once a month; handlers of grade-A raw milk once every 6 months; handlers of pasteurized milk once a year. As a consequence of the outbreak of septic sore throat spread by certified milk in 1926, consumers of this grade of milk were at once given the benefit of rather intensive milk-handler examinations. It has been possible to extend this service to include handlers of grade-A raw and of pasteurized milk on a less extensive scale but efforts of this department to secure the necessary laboratory personnel and budget that would permit the same frequency of examinations have been unavailing to date. Under present requirements the frequency of examinations of handlers of these last mentioned grades of milk is not in proportion to the frequency of examination for handlers of certified milk which more nearly approaches the ideal from the viewpoint of the public health official. This becomes increasingly evident when the situation is analyzed as in Table

V on the basis of the 1933 statistics for comparative numbers of handlers and amounts of milk produced. It is indicated in Table V that laboratory examinations on each handler of certified milk are costing annually approximately 5 times the amount expended on each handler of grade-A raw milk and approximately 10 times that expended on each handler of pasteurized milk. Furthermore, it is shown that the amount of money expended for these examinations on handlers of certified milk is 4 times as great for each 1,000 quarts of milk produced as on handlers of grade-A raw and 40 times as great as on handlers of pasteurized milk.

Although ideal from the standpoint of disease prevention to increase the frequency of examination of handlers of grade-A raw and pasteurized milk to compare with that for handlers of certified milk this seems impossible at present with the funds obtainable. Furthermore, we believe that any expansion of the work of the laboratory in milk-handler control should include periodic examinations of as many of the handlers of the ungraded raw milk

consumed by 42.2 per cent of the population of Connecticut as is feasible.

VALUE OF MILK-HANDLER CONTROL WORK

No outbreaks of milk-borne diseases have occurred among users of certified, grade-A raw or pasteurized milk in Connecticut since the inception of milk-handler control work. How much of this freedom from milk-borne disease has been due to detection of carriers by the laboratory cannot be truly estimated.

The importance of milk-borne disease in Connecticut can best be demonstrated by recounting parallel experiences with outbreaks,^{14, 15, 16, 17} due to carriers or cases working in dairies or on farms producing the ungraded raw milk not covered by milk-handler regulations. During the 77 months covered by this study there have been 7 such outbreaks which have been thoroughly investigated by the Bureau of Preventable Diseases of the State Department of Health—4 of scarlet fever and septic sore throat, 2 of typhoid fever and 1 of paratyphoid fever. The outbreaks of scarlet fever and septic sore throat have involved 328 cases with 5 deaths; those of typhoid and paratyphoid fevers, 55 cases with 2 deaths.

Assuming 3 weeks to be the minimum time an individual is incapacitated due to illness and quarantine by an attack of scarlet fever or septic sore throat and 8 weeks as the average for typhoid or paratyphoid fevers, this gives the astonishing total of 1,424 weeks, or 27 years $4\frac{1}{2}$ months, during which persons have been forced to remain away from their regular duties or from school because of preventable diseases spread by milk infected by carriers. We may summarize the economic loss from the 7 milk-borne outbreaks as the 1,424 weeks of enforced idleness, the cost of medical care for the 383 patients and the loss of 7 lives, plus the cost of 7

funerals. If this economic loss, difficult to state in dollars and cents, may result from the presence of 7 carriers in 7 dairies, the expenditure of \$48,000 in 77 months which located more than 10 times that many carriers needs no other justification.

DISCUSSION

We have devoted the greater portion of this study to analysis of our results on milk-handler specimens because we believe our data on other food handlers have not yet reached the proportions necessary for satisfactory evaluation of results. However, we call attention that we have located 16 carriers of typhoid and paratyphoid organisms among food handlers in the 32 months since January 1, 1931. Five have been detected by periodic examinations of milk handlers; 11 have been detected among other food handlers after epidemiological investigation. We point with a certain amount of pride to the fact that 5 out of 16, about one-third, have been detected before causing any known damage. We consider this a strong answer to the argument that laboratory examinations of food handlers are of little value in the absence of epidemiological investigation.

We have shown that the estimated amount expended for the detection of a single carrier varies from year to year (Table III)—in our experience from a minimum of \$387 in 1931 when 27 carriers were found to a maximum of \$3,848 in 1929 when only 1 carrier was detected. Reduced to simplest terms, this demonstrates that it may cost at least 10 times more in 1 year to locate a carrier than in another. This serves to show the impracticability of attempting to evaluate work of this type in terms of 1 year or of 10,000 or 20,000 examinations.

The conclusions that may be drawn from this study are applicable to any region to the extent that the existing

conditions are comparable to those in Connecticut. The primary condition is that the laboratory doing the food-handler control work must be doing a sufficiently large volume of work so that the unit cost per examination will be small.

SUMMARY AND CONCLUSIONS

1. Connecticut requirements for periodic laboratory examinations of food-handler specimens and the laboratory methods involved are briefly described.

2. Statistics on laboratory examinations of milk-handler specimens over a period of 77 months and on other food-handler specimens covering a period of 32 months are presented in a manner to show the total number of examinations, the number of positive examinations and the number of individuals represented by the positive examinations for each year and type of examination.

3. Statistics on 91,257 laboratory examinations of milk-handler specimens are subjected to an analysis showing estimates of the annual costs based on a unit cost per examination varying slightly from year to year. Significant figures brought forth are: total cost of the 91,257 examinations in 77 months, \$48,048; average cost of detecting each of the 71 carriers found, \$677; per capita cost for 1932, less than 2/3 cent; cost per consumer per annum less than 2 cents in 1933; cost per 1,000 quarts of milk (all grades), less than 7 cents in 1933. The cost per carrier per annum was found to vary from year to year, from a minimum of \$387 to a maximum of \$3,848.

4. A correlation of results obtained with the funds expended establishes the general utility and importance of routine laboratory examinations made periodically on important groups of food handlers in a central laboratory doing a large volume of work.

Whitney, B.S. in P.H., assistants in the Division of Microbiology, who have examined a large portion of the specimens from food handlers, and express appreciation of the kindness and interest shown by Millard Knowlton, M.D., Director of the Bureau of Preventable Diseases of the Connecticut State Department of Health, who has suggested the basis for certain pertinent calculations.

Differential Reactions in the Colon Group of Bacteria*

MAX LEVINE, PH.D., F.A.P.H.A., S. S. EPSTEIN,
and R. H. VAUGHN

Department of Bacteriology, Iowa State College, Ames, Ia.

THE brief discussion which follows will be restricted to a consideration of: (a) technics for the detection of certain metabolic end-products (acetyl-methyl-carbinol and hydrogen sulphide), which are useful for differentiation, and (b) some observations on enrichment culture media which tend to favor the growth of the citrate negative coli strains (*Escherichia*) and to restrict or exclude the citrate positive types (*Aerobacter* and *Citrobacter*).

long period recommended for incubation of cultures and the time required for the development of the characteristic eosin-like coloration (after the addition of the alkali).

A study was therefore undertaken to determine what would constitute a particularly suitable medium and test reagent to accelerate the determination in question. A comparison was made of the specially prepared dehydrated M.R.-V.P. medium (recommended by

I. DETECTION OF ACETYL-METHYL-CARBINOL

One of the objections frequently raised against the employment of the Voges-Proskauer reaction is the rather

Digestive Ferments Company) with the original Clark and Lubs medium. Observations on 181 strains which were known to be positive for acetyl-methyl-carbinol production are summarized in Table I. It is evident that with a long period of incubation (5 days), there is no significant difference between the results obtained with the two media but

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

that a shorter period of incubation (48 hours at 37° C.) as recommended for the Difco M.R.-V.P. medium, gave a distinctly larger number of positive tests.

From evidence available it is felt that the decrease in intensity and number of positive reactions when longer incubation periods are employed is due to the destruction or disappearance of acetyl-methyl-carbinol as has been reported

TABLE II

COMPARISON OF CREATINE-ALKALI SOLUTION AND 10 PER CENT KOH AS TEST REAGENTS FOR V.-P. TEST

Time after addition of test reagent	0.3% Creatine in 40% KOH	10% KOH

12 hrs.	100.0	99.4

by Paine. The long incubation periods so frequently recommended and employed are not desirable.

In the foregoing observation the test consisted of adding 10 per cent KOH to an equal volume of test culture as

originally employed by Voges and Proskauer. Recently O'Meara suggested the use of creatine powder with 40 per cent KOH as the test reagent. Table II shows a comparison of the speed of development of the pink coloration characteristic of the V.-P. test when employing 10 per cent KOH and a modified O'Meara reagent (0.3 per cent creatine in 40 per cent KOH). It is evident that the creatine-alkali solution appreciably reduced the time necessary for a positive test, 96.1 per cent of 181 strains tested showing a positive reaction within 2 hours after addition of the reagent.

The test as originally suggested by O'Meara stipulated the addition of about 25 mg. of creatine powder to 5 c.c. test cultures followed by the addition of 5 c.c. 40 per cent KOH. This procedure was found to be cumbersome. It was therefore desired to ascertain whether the reagents might not be employed as a solution. In the results reported in Table II such a solution was used and found to give satisfactory results. The question arose as to the stability of such a mixture. The effects of temperature and period of storage of the creatine-alkali mixture on the rate

of development of the V.-P. reaction are shown in Table III.

In the work reported, 24 hour cultures were employed and the reaction was taken 30 minutes after the addition of the test reagent. Preliminary studies indicated that this was ample time when employing 24 hour cultures. It is evident from Table III that the creatine-

alkali solution may be kept for 4 to 6 weeks if stored in a cool icebox and not over 2 weeks at room temperature (22° to 25° C.), whereas at high temperatures (53°-55° C.) it deteriorates very rapidly.

In order to ascertain whether the incubation period for detection of the production of acetyl-methyl-carbinol

* Figures indicate per cent positive for gas production after 48 hours.

could be appreciably shortened, a large number of strains (202) were tested in the following manner: A small loopful (1½ mm. diam.) of a young agar slant culture was introduced into about 3 c.c. of Difco M.R.-V.P. medium, the mixture incubated at 30° C. for 6 to 7 hours, after which the creatine-alkali test reagent was added. Readings were then taken after 1, 2, and 4 hours. It will be noted that in every instance positive reactions were obtained within 4 hours after the addition of the test reagent or a total period of 10 to 11 hours from the time of inoculation.

It is possible to shorten the time required for the determination of the Voges-Proskauer reaction from 2 to 5 days as recommended by *Standard Methods of Water Analysis* (A.P.H.A., 1925) to 7 to 11 hours by employing the technic herein proposed.

II. MEDIUM FOR THE DETECTION OF HYDROGEN SULPHIDE PRODUCTION

In the course of a study of a large number (401) of coli-like bacteria from eggs it was noticed that those which produced browning in the standard lead acetate agar seemed to constitute a rather homogenous group. They resembled the genus *Aerobacter* in that they grew vigorously in citric acid as a sole source of carbon, but differed from this genus in that they were negative with respect to the V.-P. reaction and positive with the methyl red test, thereby resembling the genus *Escherichia*. Other differential characteristics of this group of bacteria for which the generic term *Citrobacter* has been suggested, are summarized in Table V.

The H₂S reactions in the standard lead acetate medium were not clear-cut and the apparent significance of this

differential test for the group under consideration led to a study of media for accentuating the test. The following medium was found to be particularly suitable for H_2S production and detection:

Proteose peptone (Difco)	20 g.
K_2HPO_4 (anhydrous)	1 g.
Bacto agar	15 g.
Ferric citrate	0.5 g.
Distilled water	1,000 c.c.

Dissolve by boiling, tube and sterilize at 15 lb. for 15 minutes. Inoculation is made preferably from 24 hour broth cultures by stabbing into the middle of the solidified medium and also down the side of the medium in contact with the inner surface of the tube.

III. TEMPERATURE OF INCUBATION AS A DIFFERENTIAL TEST

The use of high temperatures for the isolation of members of the colon-group was first stressed by Eijkman who recommended glucose broth at $46^\circ C$. The importance of stipulating whether the temperature refers to the incubator or the medium proper has been frequently stressed* and this is evident also from Table VI.

It is evident that with an incubator temperature of $45-46^\circ C$. (temperature of the medium $43-44^\circ C$.) the *Escherichia* strains grew well in the Eijkman medium and Standard Lactose Broth, but some strains were inhibited in brilliant green bile. The *Aerobacter* strains were markedly inhibited in all of the media. It is particularly interesting to note that whereas 77.8 per cent of the *Citrobacter* strains showed gas in the Eijkman medium, none were positive in lactose broth.

With the temperature of the medium raised before inoculation and maintained at $45.5-46^\circ C$. gas was not produced by any of the *Aerobacter* or

Citrobacter cultures, although growth was frequently evident; but the *Escherichia* strains were also markedly inhibited as respects gas production at that high temperature.

IV. A BORIC ACID MEDIUM FOR GROWTH OF ESCHERICHIA AND INHIBITION OF AEROBACTER AND CITROBACTER STRAINS

Numerous media have been reported for growth of *Aerobacter* and closely related strains with the exclusion of the members of the genus *Escherichia*, but a medium which exhibits the reverse phenomenon would be very useful. In 1921 Levine suggested that boric acid seemed to exert a greater inhibitory action on aerogenes than upon coli strains. The following medium has been tested with a large number of strains with the results indicated in Table VII, and seems to be very promising. The cultures of the genus *Aerobacter* were very markedly inhibited with only 6.1 per cent showing gas in 48 hours with 0.325 per cent boric acid. The *Citrobacter* strains were all negative whereas of the 150 *Escherichia* strains tested, 97.3 per cent produced gas.

Composition of medium:

Proteose peptone (Difco)	10 g.
Lactose	5 g.
K_2HPO_4 (anhydrous)	3 g.
Andrade indicator	10 c.c.
Boric acid	3.0-3.25 g.
H_2O (distilled)	1,000 c.c.
Sterilize at 15 lb. for 15 minutes.	

SUMMARY

A technic is described for detecting the production of acetyl-methyl-carbinol (V.-P. reaction) in 6 hour cultures. The test reagent consisted of 0.3 per cent creatine dissolved in 40 per cent KOH. This creatine-KOH solution was employed satisfactorily for 3 weeks when stored at room temperature and for 6 weeks when stored at icebox temperature.

* Private communication Brown and Skinner.

TABLE VII
EFFECT OF BORIC ACID ON GROWTH OF COLON-GROUP AT 37° C.

Period of Incubation	24 hrs.		48 hrs.	
Concentration of Boric Acid	0.30%	0.325%	0.30%	0.325%
Cultures observed	Per cent showing gas			
<i>Escherichia</i> (150 strains)	92.7	87.3	97.3	97.3
<i>Aerobacter</i> (181 strains)	1.7	0.6	13.8	6.1
<i>Citrobacter</i> (57 strains)	0.0	0.0	0.7	0.0

A medium containing proteose peptone (Difco) and ferric citrate, as an indicator, was found to be particularly satisfactory for the detection of H_2S production, and this phenomenon served to differentiate the strains which were V.P. negative, methyl red positive and citrate positive (genus *Citrobacter*), from the other members of the colon-aerogenes group.

With an air temperature of 45–46° C., employing the standard lactose broth medium, all (31) strains of *Escherichia* observed produced gas, whereas all (54) *Citrobacter* strains failed to produce gas and of 181 cultures of *Aerobacter*, only 3.9 per cent produced gas. With a temperature of 45.5–46° C., in the medium proper, marked inhibition of the genus *Escherichia* was noted (only 38.7 per cent producing gas), and in no instance was gas produced by any of the *Citrobacter* (54) or *Aerobacter* (181) strains examined.

A medium containing boric acid is described which may be useful for detection of the genus *Escherichia* and to exclude or inhibit growth of the genera *Citrobacter* and *Aerobacter*. With this medium 97.3 per cent of 150 strains of

Escherichia showed gas whereas only 6 per cent of 181 strains of the genus *Aerobacter* produced gas in 48 hours at 37° C. Gas was not produced by any of 57 strains of the genus *Citrobacter* tested.

Relative Values in Tuberculosis Case Finding

ROBERT E. PLUNKETT, M.D.

*Director, Division of Tuberculosis, New York State Department of Health,
Albany, N. Y.*

“**N**USQUAM est, qui ubique est” (He who is everywhere is nowhere) has its application to the predominant thought in the minds of many social workers and others who are interested in tuberculosis. The attractiveness of doing something new, the human appeal of children to the masses, has diverted altogether too many workers in tuberculosis from case finding work in the fertile field of cases, contacts, and doubtful cases, to the less productive and the more expensive method of case finding among school children. Unless the home and contacts of every reactor are studied epidemiologically, little, if anything, is really achieved. The importance of concentrating efforts upon cases, contacts, and doubtful cases of tuberculosis cannot be overemphasized.

The valuable work in the field of childhood tuberculosis performed by several research groups should be continued. However, those in charge of public tuberculosis programs, particularly where public funds are used, should take stock of the results obtained and center their efforts in a manner conducive to the best possible results. What percentage of public funds may be used for research is a question; but no one will deny that those charged by the people with a special piece of work should use known and proven methods, diverging into untried, unproved and

less productive paths only if there is time and money left.

The proponents of the tuberculin testing of school children seem to forget, first, that for all practical purposes there is a difference between infection and disease, or if they are fully cognizant of this difference, they neglect to emphasize it to the nurses, social workers, and parents concerned with the children tested; and second, that among grade school children tuberculosis is usually a benign disease. In upstate New York only 3.2 per cent of all tuberculosis deaths occur in the age group from 2 to 14 years. Lack of appreciation of these facts creates confusion and no little apprehension in the minds of parents and others. Not infrequently we hear it said that a child who reacts to tuberculin is a potential consumptive. In the absence of evidence of manifest tuberculosis, or contact with an open case, are we not stretching our imaginations in saying that such a child is potentially tuberculous from a disease standpoint? Are we not tending in another manner to lead parents and children to become pathological minded?

In summarizing the conclusions of many workers, Korns,¹ Slater,² Chadwick,³ Hetherington and McPhedran,⁴ Bridge and Stokes,⁵ Ryan,⁶ Hart,⁷ and Bernard,⁸ we find practically a unanimity of opinion regarding the in-

fluence of age, contact, and population density upon the incidence of tuberculosis. As children become more mobile the opportunity for accidental infection by casual, direct, or indirect contact increases. The more concentrated the population, and the higher the death rate, the greater the incidence of infection. Many workers have shown that tuberculosis is found from 5 to 9 times more frequently among contacts than in the population as a whole.

In our study⁹ of 537 freshman students of New York State normal schools, ages 16 to 19, 33.4 per cent of the total group were positive to 0.1 mg. of tuberculin. A study of the residence of the group tested up to the time they entered school, on the basis of population, showed that of those re-

siding in communities of less than 2,500, 28 per cent were positive, in communities between 2,500 and 10,000, 36.5 per cent were positive, and in those of 10,000 and over, 42 per cent were positive. Only 1 case of adult type tuberculosis was found in the entire group.

Chart I, taken from the Medical Research Council's *Special Report, Series No. 164*, by P. D'Arcy Hart, shows the percentage of reactors among non-contacts and contacts both in London and Philadelphia.

It will be seen from this chart that (a) the curve for home contacts runs above that for non-contacts and (b) the shapes of the two curves differ. This difference in shape may have some epidemiological interest. It suggests that the tuberculinization of home con-

CHART I

Tuberculin reactions of non-contacts and of home-contacts of pulmonary tuberculosis (From Schlesinger & Hart, 1930)

U.S.A.: Philadelphia. Opie & McPhedran (1926): home-contacts of pulmonary tuberculosis, hospital class (? includes a few cases of clinical tuberculosis). Non-contacts of tuberculosis, hospital class.

England: London, 1929. Home-contacts of pulmonary tuberculosis, hospital class, all clinically non-tuberculous.

Non-contacts of tuberculosis, hospital class, all clinically non-tuberculous.

tacts has its maximum rate in infancy and early childhood, whereas the tuberculization of non-contacts occurs at approximately the same rate from birth to manhood.

Observers in other communities have published comparable figures regarding the incidence of infection. Bridge and Stokes report that they found 2.5 per cent of rural school children with some pathology by X-ray against 12.1 per cent of the children who were examined because of contact.

Chadwick¹⁰ says, "Our problem is to prevent infection. No one will deny the manifold benefits of complete freedom of contact with tubercle bacilli." Hetherington¹¹ says that "since 80 per cent of the high school children of Philadelphia have been exposed and become allergic, it is impracticable to avoid all contact with the tubercle bacillus."

It may be possible in a strictly rural community to avoid infection, especially in the pre-adult ages, but when it is found that the incidence of infection among the general population in adult life approaches the amount found among contacts in children is it not more practical again to emphasize the importance of contact and endeavor to prevent continued, or massive infection? To be sure, this is the goal of all tuberculosis workers, but a review of the activities of many of them results in the conclusion that they are making many detours in locating the goal as well as in attempting to arrive there.

In the light of our present knowledge the important fact in the development of tuberculosis is the intimacy of contact. The greater the opportunity for repeated and massive infection the greater the opportunity for breakdown. If this be so, should we not strive to minimize the chance for such a degree of infection by finding and segregating the case and treating it with the hope of making it sputum negative?

Unquestionably, the work in the schools has made many more people tuberculosis conscious, and considerable improvement in the technic of public control may result from their increased interest, but prevention still remains the fundamental principle of tuberculosis control.

The word "prevention" naturally stimulates thought regarding the *modus operandi* by which an effective program may be obtained. For years case finding has been the alpha of tuberculosis control. When we speak of case finding today, the practice of testing wholesale groups, especially groups of school children, comes to the foreground in the minds of many. It is not with any lack of appreciation of the value of this research work that emphasis is laid on the need of more intensive work among cases, contacts, and suspects. On the contrary, there is much to learn regarding the genesis of tuberculosis before we can afford to be dogmatic in our statements about it. Further studies should be made, and to obtain the most effective results they should be conducted by groups equipped to make them in a thoroughly scientific manner. In a disease having the characteristics of tuberculosis long periods of observation and study are necessary before an answer can be found regarding its genesis.

The support of the practising physicians in any tuberculosis service is paramount. They should assume a prominent place in the prospectus of every program. They see most cases before there is any suspicion of the presence of tuberculosis, and when, by experience, they learn that both they and their patients are benefitted, they become active participants in the program of tuberculosis control.

There appears to be no proof available that any method of approach to case finding in tuberculosis can produce results comparable in cost and energy

expended with that concerned with the combination of morbidity and mortality statistics and the coöperation of the practising physicians. For more than 14 years the New York State Department of Health has conducted a consultation clinic service in counties having no special tuberculosis service. The average resident death rate for these counties over the past 5 years has been 44.7 per 100,000 population. Practically all the physicians in the communities in which these clinics are held refer contacts of dead and known cases, as well as patients who may show some suspicious symptoms or signs of diseases of the lungs. The extent of the coöperation of these physicians may be interpreted by the number of their patients attending the clinics who have the benefits of public health nursing follow-up in their homes. Less than 6 per cent do not have the benefits of this service because of physicians' refusals.¹² Comparing our case finding figures with some of the largest childhood programs, it is found that 8 or more cases of adult type tuberculosis are discovered for every 1 in those programs. Of every 20 new patients examined at our clinics 1 new case of adult type tuberculosis is discovered. Of all the persons examined, 1 new case of adult type tuberculosis is discovered in every 41. Moreover, we find 12 times more clinical tuberculosis among adolescents and adults than among the children.

In conclusion, the X-raying of the entire population once or twice a year might result in the discovery of every case of tuberculosis. This being impractical, it is urged that those phy-

sicians charged with the responsibility of tuberculosis control intensify their efforts among cases, contacts, and patients referred from private practice by physicians. In every community these groups constitute the major part of the tuberculosis problem. When the work in these groups is thoroughly accomplished, then other groups, school children, and industrial groups may profitably be studied. Incidentally, if the work is thoroughly performed in the fertile field above mentioned, a large number of the cases which may be discovered by the other methods will already have been disclosed by this less expensive and more profitable service.

Development of Public Health Administration in the Province of Quebec*

ALPHONSE LESSARD, M.D., F.A.P.H.A.
Director, Provincial Bureau of Health, Quebec, Que.

THIS is the second time during 2 years that I am asked to show you something of the development of public health in the Province of Quebec. At the Montreal meeting, I spoke on rural sanitation from a Provincial standpoint and, after a brief history of what public health administration was in the Province during the years prior to 1926, I tried to demonstrate how great progress had been made since then through the institution of the County Health Units System.

Let me say, in order to complete the statement which I then made, that the Province of Quebec has now 28 Health Units covering 36 counties with one more in prospect, to be in operation in a few weeks; that more than 900,000 people are now protected by that system, out of a possibility of 1,700,000, constituting our rural and semi-rural population; that, thanks to this logical and scientific organization, our general mortality rate fell from 13.5 in 1926 to 11.4 in 1932, and our infant mortality rate from 142.0 per 1,000 living births to 94.2 in the whole Province and 85.8 in the Health Units.

But, it is in the realm of the fatalities caused by infectious diseases that this decrease has been particularly remarkable. In 1926, the whole

Province lost 4,144 individuals by contagious infections, a rate of 158.3 per 100,000; and in the counties, which were organized later on, 1,705, a rate of 204.1. In 1932, those deaths numbered 2,363, a rate of 80.8 all over the Province, and in the units the number fell to 690, a rate of 76.5, marking a decrease of 48.9 per cent for the whole Province of Quebec and of 62.5 per cent for the counties provided with health units.

There is nothing against the facts. The demonstration is now done and, in my mind, it is proved beyond all doubt that in a country where the authorities are willing to raise up the standard of public health, nothing is comparable to the system which we copied in part from yours in the United States, and which was recommended to us by the Rockefeller Foundation, taking into account the modifications necessitated by our particular conditions.

One of these particularities, which I mentioned at the Montreal meeting, was the unity of direction put in the hands of the central office, the complete jurisdiction of this body all over the local units, and the adoption of the principle that the health organization in a county and the authority over it must not be left in the hands of local individuals—as well disposed as they may be—subject to numerous changes of opinion in the mind of the municipal authorities.

* Read before the Health Officers Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

Up to the last winter, the fate of every county health unit in our province, as the thing happens to be in every country where this system exists, I think, was left in the hands of local authorities appropriating a certain sum of money toward their maintenance and receiving the help of the state. The result was that during a period of economic depression like the one we are now passing through, it was to be feared that our county councils would be led, due to the circumstances, to neglect the public health viewpoint and to let a system toward which so many efforts were consecrated, fall to pieces and the situation be turned to what it was many years ago.

We, of the Provincial Health Service, estimated that that would have been a disaster, and we tried to bring our Ministers to the idea of making permanent and compulsory all the existing units and of giving to the Cabinet, on the recommendation of the Department, the power of establishing new ones in the remaining counties, at the authorities' convenience.

We were fortunate enough to succeed in our efforts, and the law assented to on April 13, 1933, adopted by the Legislature 2 weeks previously, was brought into the Statutes of the Province of Quebec, saving the existence of a system to which our population owes so much.

Considering the difficulties with which all our municipalities are suffering at present, the legislators decided, in order to alleviate the burden of taxation for public health, to impose as a contributory share by each municipal county corporation provided with a health unit, a small sum calculated on the basis of $1\frac{1}{2}$ cents per 100 dollars of the amount of the taxable valuation, appearing in the valuation rôle in force in each of the municipalities, and 2 cents in the independent cities and towns situated in the counties and hav-

ing a population of 4,000 people or more, but less than 20,000. The balance of the budget of each county health unit is to be provided for by the Provincial Government.

The same law repeats the disposition of the old one and puts the county health units under the direction and control of the Director of the Provincial Bureau of Health.

This legislation which we, at home, consider far advanced, brought an element of security to the work toward which so many efforts have been concentrated during the last few years.

It would be useless to have a good law in the Statute Book and to neglect the important part of the continuity of the work which was inaugurated at the beginning.

Starting from the principle that an efficient public health work rests on the base of an adequate education of the people, and that education must be impressed upon them in the early years of life, we intensified, all over the territory covered by our organization, the babies' clinics, which from the day they were inaugurated, met with so much success in all our counties.

As you know, infantile mortality was, with tuberculosis, the main scourge affecting our population. A mortality rate of 142.0 per 1,000 living births in 1926 was a thing which we were not proud of, and we may say that the decrease to 94.2 in 1932 for the whole Province, and to 85.8 in the units, was due to the net-work of clinics spread over the territory provided with our organization.

These clinics are held in every municipality of the counties by our health officers, assisted by a public health nurse. The attendance of babies, which was for the fiscal year 1932-1933, 83,083, has increased to 3,500 per week, which signifies that during the present fiscal year, 182,000 babies will be seen by our officers.

In a number of these clinics, preschool children attend also, and we instructed every health officer at their last general meeting, to give special attention to this attendance of preschool children, keeping in view the point that if we succeed in improving the health of the young generation we will secure for the future a healthy population.

Before leaving the question of child protection, I wish to say a word of our generalized campaign of immunization against diphtheria in all our units.

We took as granted that immunization against diphtheria is a matter of prevention and not of treatment, and so must be left in our hands. We have all due consideration for the privileges of the medical practitioner and we understand perfectly that he is entitled to the right of himself practising immunization against diphtheria among his clients when they ask him to do so. But, in the presence of a situation like the one which happened in 1927, when the Province of Quebec lost 467 children, victims of diphtheria, we considered that it would have been a national crime not to take the matter in hand and not to offer the population the advantage of being protected against that dreadful disease by all means at our disposal. We decided to institute free immunization clinics in all our county health units, offering immunization by toxoid, to the parents willing to have their children protected.

So far, the proportion of immunized children in the county health units, speaking generally, nearly attains 75 per cent; in some counties this reached 100 per cent, with the result that on July 1, 1933, 150,137 children were safe from the disease and the mortality rate from diphtheria was reduced to 6.5 per 100,000 in the Province.

I would like to say a few words of the System of Travelling Tuberculosis Clinics which we inaugurated and de-

veloped in the last few years in our counties.

Our health units, for the purpose of tuberculosis control, are divided into 5 districts each in charge of a full-time tuberculosis specialist, travelling from one municipality to another, provided with a portable X-ray apparatus and who examines the chest of every person willing to be examined, on a certain day of the week announced the previous Sunday by the parish priest from the pulpit.

During the last fiscal year approximately 25,000 were so examined by these diagnosticians, brought or sent to the clinics by their family doctor, the nurses, and the school commissions. Numbers of them were perfectly ignorant of the state of their lungs, and the good advice given in the following week by the district nurse had the effect of teaching them the way of protecting themselves and their surroundings.

We, in the Province of Quebec, are short of a considerable number of beds for the tuberculous; as a fact, we should have 1,300 more of them than we have at present; this time of financial difficulties prevents the public authorities from establishing new sanatoria and hospital sanatoria, but in the meantime the educational campaign conducted by our men constitutes an element of protection and improvement of this situation. I consider that it is a good way of eradicating this scourge from our population.

We also established, 4 years ago in the Province of Quebec, what is called in France "L'Oeuvre Grancher" and which, according to my information, does not exist elsewhere in America, and is destined to accomplish much good.

This protection system consists in taking from poor families in the cities, where there exists an open case of tuberculosis, the children from 2 to 13 years of age, and putting them in the

country, in farmers' families having no children or whose children have left the home.

Statistics in France demonstrate that children, if left in their families where a case of open tuberculosis exists, contract the disease in the proportion of 60 per cent and die of tuberculosis in the proportion of 40 per cent, while the percentage of mortality from tuberculosis among children so placed in the country, is less than 1 per cent.

Taking those facts into account and wishing to add another way of fighting a social evil which has done considerable harm in the past, we began at the end of 1929 that kind of social work in the District of Montreal, and a year later, in the District of Quebec and the District of Trois-Rivières.

Through the intermediary of anti-tuberculosis dispensaries in these 3 cities, the finding of cases to benefit by the system was done by special nurses, and we took from the slums, where they lived, nearly 500 children with the written consent of the parents, and placed them, paying for their board, clothing, school, and medical care, in well-to-do farmers' families in the rural counties situated in the vicinity.

If it was not for the financial difficulties of the Government, that number of 500 would have been doubled or tripled during that period of 4 years, but, unfortunately we had to restrict somewhat our activities according to the means at our disposal. However, as soon as the situation shows an improvement we will of course accelerate the movement.

An inspection tour which I made 2 months ago in the counties in which children from the City of Montreal were

placed, showed me what effects we may hope for from such a system.

1. First of all, the children's health is perfect, and we may consider them in the future safe from tuberculosis, which would have been surely their lot if they had remained in their families.

2. All those children living in good conditions and comparing their present situation with the one they were suffering with while in the cities, are anxious to remain on the farm, and I consider this somewhat as an element helping the "back-to-the-land" movement.

3. The foster parents having had no children in the past, or having seen their children leave the home, entertain toward the children so placed in their midst a real feeling of paternal love, and I saw several of them weeping at the idea of the separation from those children. Numbers of them desire to adopt them and to make them their heirs.

This is in a few words a resumé of the work of the Children's Family Placement toward the protection of children against tuberculosis. It is not the only medium of fight which we may adopt, or which we adopt—it is one of them; and I am very confident in the future results.

This is only a part of the activities relating to the progress of public health administration in the Province of Quebec for the last years. We are not so presumptuous as to think that we have found out something new, but we have tried to adapt to our situation the methods that have proved a success elsewhere, and, thanks to the help given by our Governmental authorities, and, the thing must not be forgotten, by that great philanthropic institution—The Rockefeller Foundation—we have made a few steps forward, hoping to advance further in the road of an improved and perfect public health.

Diphtheria Prevention in Chicago

The Health Officer's Problem

HERMAN N. BUNDESEN, M.D., F.A.P.H.A.

President, Board of Health, Chicago, Ill.

IN approaching the matter of diphtheria prevention in Chicago, it was first necessary to find out just what our problem was, so we turned to the past records.

In 1929, an average year in the history of diphtheria, there were 6,012 cases and 513 deaths. For the 10-year period, 1920-1929 inclusive, there were 54,420 cases and 4,321 deaths. During those 10 years a more or less continuous effort was made to get the school children immunized against this disease, but the morbidity and mortality did not appreciably decrease. We now know that procedure did not materially reduce diphtheria, because about 60 per cent of the deaths were occurring in children under school age, who were not being reached by our program. That this same problem holds true in the country at large, is attested by the following statement recently made by the Metropolitan Life Insurance Company:

The sad fact remains that in 1932, according to estimates, more than 5,000 children, most of them under 5 years of age, died from this disease.

We are asked:

1. How was the marked and rapid reduction of the diphtheria death rate and case rate in Chicago, brought about?

By inoculating more than 90 per cent of the preschool children with toxoid or alum toxoid.

2. How can this very low rate be permanently maintained?

By continuing to inoculate every new baby just as soon as possible after he reaches 6 months of age.

3. How can this rate be further reduced?

I do not know. The answer to that question may be forthcoming at this meeting today, just as the results obtained in Chicago were brought about through the knowledge gleaned from the reports of this section 2 years ago.

A number of you remember Godfrey's most excellent paper read at the meeting of the American Public Health Association in Montreal in 1931.¹ It started many health officers into action. He pointed out that the experiences in New York State and in Detroit, and in other cities during the preceding 9 years, seemed to indicate that if 35 per cent of the preschool children and 50 per cent of the school children were immunized against diphtheria, widespread outbreaks of this disease would not occur.

Fortified by those facts, we in Chicago set as a minimum goal, the immunization of 35 per cent of the preschool children and 50 per cent of the school children, with the most efficient immunizing agent known at that time.

Material Used—At the start of this drive, the consensus of opinion was that

¹ Read before the Health Officers Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

toxoid was superior to toxin-antitoxin. After our drive started, reports reached us that alum toxoid was even better than plain toxoid. Experiments with material kindly furnished by Dr. William H. Park, indicated that alum toxoid was the best immunizing agent to use. Three groups of children were tested, with more than 250 children in each. The first had received commercial toxin-antitoxin. Seventy-two per cent of them were found to be immune after 1 year. The second received toxoid sent by Dr. Park, and 95.9 per cent were immune within 6 months. The third group were given the same toxoid to which alum had been added, and 100 per cent became immune in 6 months. Since October, 1932, alum toxoid has been used exclusively.

To find out the most effective interval between the doses of alum toxoid, another series of experiments was undertaken. Two groups of children were tested, there being more than 250 children in each. It was found that the results were as good when 2 doses were given 1 week apart as when given 3 weeks apart; therefore, the 1-week interval was adopted.

The List of Mothers—The most difficult problem confronting the health officer is to find a way to reach all children under school age. Fortunately, there is on file in the Board of Health a list of over 300,000 mothers, representing about 425,000 living children in Chicago, born since August, 1925. This list is kept up-to-date by sending to all mothers, every month or two, copies of our child health literature. A house-to-house canvass of the entire city by nurses showed that the list was remarkably free from error, and contained the name of nearly every child of preschool and early school age. Such a file is invaluable in any public health campaign, and, was one of the most important things in making our campaign successful.

Statistical Procedures—Name stencils were run through an addressograph machine, producing a name card for each baby. The city was divided into 140 districts, the cards were distributed according to these districts, and each was assigned to a nurse. The nurses routed the cards in each district, for the purpose of making calls. In calling, the nurse's duty was to explain to the parents the need for immunization against diphtheria. She continued going into the home where an unimmunized child lived, and returned repeatedly until the child was inoculated, or until the parents definitely refused to have it protected.

As soon as the child was inoculated, a report was sent to the Board of Health, and a tab was put on the addressograph plate, by means of which a selector device kept the plate from having a card printed when it was run through again. No more visits were made in homes where the children were inoculated. We were able to keep an accurate record of all preschool children, both inoculated and not inoculated.

Early in 1933, we made maps, coloring each district according to the number of uninoculated children who remained in it. Although at that time the number of inoculated children was approximately 80 per cent, far more than enough to control diphtheria, according to Godfrey's figures, a number of cases were occurring each day, and diphtheria was far from being completely under control. When the colored map was carefully studied, it showed that the 80 per cent of children inoculated were not evenly distributed. For example, in February, 1933, one district, containing over 21,000 children, had 595 children still unprotected. Such an area within a large city is essentially a small unprotected city, in which diphtheria cases and deaths may persist, and from which the disease con-

tinues to be spread even though a large majority of the total child population is immune.

In order to obtain complete protection for the entire community no such local groups of unprotected children should be permitted to exist. Therefore, each time the cards were run through the addressograph machine, and a map made from the cards for the uninoculated children, our efforts were concentrated on those districts showing the largest number of children not yet protected.

Infant Welfare Station Centers—During the campaign, the 40 infant welfare stations, as well as the public and parochial schools, were used as diphtheria prevention stations. Our aim was to immunize every child under 6, in each station district. During the week, the nurses referred all mothers who had signed consent cards, and who were unable to afford a private physician, to the welfare stations on the following Saturday morning. If they failed to report or did not bring the children in for the second injection, the nurse made several return calls, and, as a last resort, staff members were sent to the homes to give the injections.

School Centers—Every school was used as a diphtheria prevention center. Arrangements for this were made with the Boards of Education of both the public and the parochial schools. Before a date was set for giving the injections in a given school, the principal or sister superior was consulted by the superintendent of the school, and by the field nurse, hence, the school authorities were prepared when the immunizing staff arrived. The nurses visited every home in the district where there was an uninoculated child. The mothers signing the consent cards were given an appointment to go to the school, if they could not afford a private physician. The consent cards were given to all school children under 10 years of age

to take home for signature. Each district was handled separately, and only a few of the 600 schools of the city were covered at a time.

Special Parochial School Routine—The mortality statistics for 1929 showed that 275, or over 50 per cent, of the deaths were occurring in persons of the Catholic faith, and, of these, 90 per cent were in children under 10 years of age. Therefore, a special folder containing a letter from his Eminence, Cardinal Mundelein, and a letter from the President of the Board of Health, was prepared and distributed from all of the Catholic churches, following a statement of explanation by the pastors. This work was aided materially by Dr. Louis D. Moorhead, the Cardinal's Medical Representative, and a consulting member of the Board of Health. The Sunday before the injections were to be given in the parochial schools, the pastor announced them to the congregation. He also urged the people to bring the children in for the treatments. As the congregation left the church, each person received a copy of the folder containing the letter from Cardinal Mundelein. These folders were printed in 8 languages. The splendid coöperation given us in this part of our work, contributed greatly toward the success of our program.

Before any child was inoculated, it was required that the parent give written consent; but only 1 out of every 3 children of the many thousands whose parents signed the consent cards, was actually brought in to the stations for the injections. Most of these families were so poor that they did not even have clothing or carfare to come to the station. Some others were indifferent, or claimed that they were too busy; so transportation buses were provided. This did not prove successful, as many mothers who promised to be ready at a given time, failed to keep the appointment.

Diphtheria Buses—Finally, to overcome this difficulty, buses were fitted up as traveling health centers, and these were found most effective. They were manned with doctors and nurses, and equipped with all the materials for giving toxoid injections. Before the bus started out, the nurses preceded it through the district, making appointments with the mothers to meet it at a certain corner within a few blocks of their homes. The inoculations were given then and there. If the mothers did not keep the appointments, later on, the bus went directly to the homes, to give the treatments. To help in this work, ice cream and cracker jack, donated by public spirited citizens, were distributed to the children who received the inoculation. As can well be imagined, this created a lot of enthusiasm on the part of the children. It had been difficult to get 10 or 12 children to the bus, but when it was learned that ice cream and cracker jack were being given away, the attendance jumped into the hundreds.

The Family Physician's Part—The coöperation of organized medicine is desirable in the successful conduct of any public health program; therefore, every appeal, particularly the personal contacts by nurses, was preceded by a plea that the children be taken to the family physician to receive the toxoid. Of course, when economic conditions did not permit this, free service was given. The private physician is the logical man to carry on this diphtheria prevention work and every effort should be made to encourage him to assume that responsibility.

When the nurse was told by the parent that the family physician would inoculate the child, she took down the name and address of the doctor and reported it. Then a letter was sent to the doctor telling him that the mother was going to take her child to him for the toxoid treatments. The physician

was asked to see the patient and to notify the Board of Health when the last injection was given. Approximately 15 per cent of the inoculations were given by the private physicians.

Objectors—Whenever a mother stated that she or her husband was opposed to serums or vaccines, for religious or other reasons, and a number of different nurses had called on her without success, the addressograph plate was marked with a red tab, and no further calls were made. If the parents flatly refused and gave no reason, the red tab was not at once put on. Instead, the nurse returned a number of times in an effort to sell the family on the need for the toxoid injections. It is interesting to know that of over 425,000 children on our list, of whom over 90 per cent are now inoculated, only some 14,000, or about 3 per cent, represent parents who objected.

Reactions—When hundreds of thousands of children are given toxoid injections, it is easy to see that occasional infections may occur. There is always the human equation to consider. We had some few sore arms. We found that one group of sore arms occurred in children at a certain station. The toxoid used at that station was found to be sterile. The organism was a hemolytic streptococcus. Cultures made from the throat of the doctor showed the same type of hemolytic streptococcus. From that time on we insisted on throat cultures from all of the attendants regularly engaged in inoculating groups of children.

Handling of Cases and Contacts—If we have faith that a negative Schick test, properly done, means protection against diphtheria, we should have the courage to put that faith into execution; therefore, May 1, 1933, our previous plan of giving 1,000 units of antitoxin to all children in contact with an active case of diphtheria, was discontinued in those under 10 years who had pre-

viously been given toxin-antitoxin or toxoid at least 2 weeks before the exposure. Those who had received toxoid previously were given the Schick test, and if found to be negative, were given no further treatment, but watched by the health officer from day to day. Of these diphtheria contacts who had previously been given toxin-antitoxin or toxoid, 18 were found to be Schick negative and only 1 positive. None developed diphtheria.

Diphtheria contacts under 10 years of age, who were found to be Schick positive, and who had a negative throat and nose culture, were at once given the toxoid. If over 10 years of age, 1,000 units of antitoxin were given. None of the Schick positive contacts with a negative nose and throat culture developed diphtheria. The plan contemplated that if the diphtheria contact was Schick positive, and had a positive nose and throat culture, without any clinical symptoms of diphtheria, he was to be given 1,000 units of antitoxin at once, but no diphtheria contacts with both positive Schick and positive nose and throat cultures have been found.

We adopted this plan for handling contacts: (1) since more than 90 per cent of the children had been inoculated against diphtheria, it was felt that there would be few contacts who were susceptible to the disease; (2) we believed it would prove to mothers that we had faith in the toxoid injections; (3) the plan avoided making children serum sensitive, as often happens when they are given antitoxin. Diphtheria contacts who had received antitoxin recently were not given a Schick test at this time, but 5 weeks after every recovered case of diphtheria was terminated an effort was made to have that case and all contacts who had been given antitoxin, actively immunized with toxoid.

Routine for Future Control—We have now protected the large mass of the child population under 10 years of age, and with the machinery now in operation we feel that we can easily continue to inoculate at least 90 per cent of the approximately 50,000 babies that are born every year, soon after they reach the age of 6 months. This is now being done as follows: When babies become 6 months of age, the parents are sent a bulletin which outlines the hazards of diphtheria and the need for protection against it. The nurse also makes a call at the home, urging immunization. If the immunization is not carried out, she returns again at 8 months, 10 months, 1 year, and thereafter once a month. By this method, we have succeeded in getting 40 per cent of the children inoculated by the time they are 10 months of age, 70 per cent by 12 months, 80 per cent by 14 months, 86 per cent by 16 months, and 90 per cent by 18 months. By continuing this program, we feel sure that diphtheria will become a rare, if not an extinct disease in Chicago. The effectiveness of this type of campaign is attested by the following figures: In 1929, after 10 years of the usual type of diphtheria campaign, from January 1 to October 1, there were 347 deaths. In 1933, after our specialized, intensive drive in preschool children, there were 7 deaths in a corresponding period of 9 months. In the last 16 weeks there has been only 1 death. Since July 22, 1933, there has not been a single death from diphtheria in Chicago.

CONCLUSIONS AND SUMMARY

In the diphtheria prevention campaign in Chicago, the following measures and methods were found to be important:

1. The constant use of a file containing an up-to-the-minute list of the

names and addresses of all preschool children in the city.

2. The use of alum toxoid which made it possible to produce a higher degree of immunity against diphtheria than by other immunizing agents. In 100 per cent of the cases given 2 injections of alum toxoid, at weekly intervals, negative Schick tests were obtained in 6 months, with practically no reactions.

3. Repeated personal contacts and home calls, by the public health nurse, to urge and sell the idea of immunization.

4. The traveling health centers, which took the inoculation to the child, when

that child did not come to the welfare station.

5. The campaign of the Catholic Church which aided materially in overcoming resistance among many of the foreign born, who tended to resent what they considered interference with their personal liberty.

6. The coöperation of the medical profession.

7. The educational appeal through bulletins, posters, letters, the radio and the newspapers.

The Doctor's Job

"To my mind, these are the attitudes of an honest, earnest, well trained doctor of today:

He is unafraid. The doctor's job, whether his present concern is private practice or public health, is paramount to the nation's welfare. Whatever the political framework of tomorrow, there will be a place for him and a place in the sun.

He continues to learn. He feels a maladjustment in the society he serves, and he seeks to understand it in the whole as well as in part. He considers with an open mind at least two sides of a suggestion: his own and the patient's. He is eager for new information; he faces facts.

He participates. If he is a practising physician, he is active in obtaining and maintaining a first class health depart-

ment for his community. If it is partisan-ridden, he helps to turn the rascals out and to change the rules so that a good job is possible. If he is a health officer, he keeps close to clinical medicine and medical research. He takes counsel with private physicians; he is familiar with their problems.

He plays fair. He is not petty himself nor will he tolerate the factional bitterness which has made so many a medical organization the synonym for strife.

And last, he looks ahead, in terms of the community and the nation, as well as himself and his profession. He is a good citizen."—Thomas J. Parran, Jr., M.D., Health Services of Tomorrow, *Transactions of the College of Physicians of Philadelphia*, 2, 1:75, 1934.

Contribution of Public Health Nursing to Maternity, Infancy, and Preschool Age Group^{*}

AGNES G. TALCOTT, R.N.

Director of Nurses, City Health Department, Los Angeles, Calif.

AS we look back along the way which public health nursing has travelled we note general trends and tendencies. With the modern public health movement, prevention became the keynote.

Obviously the preventive program should be started with the individual before birth. If it is true, as Dr. Haven Emerson has said, that the pregnant woman, the little children, and the sick-a-bed are the only groups in the community genuinely interested in their bodies, these groups afford the public health nurse her opportunity for effective health teaching.

The prevention of maternal deaths and the saving of infant lives are public health activities. Upon the shoulders of the public health nurse rests largely the responsibility of getting in touch with prospective mothers as early in pregnancy as possible and urging the necessity for continuous medical and nursing supervision throughout the maternity cycle. The public health nurse explains and demonstrates to the mother the principles of personal hygiene and helps her apply them in the everyday care of her baby.

The interests of the preschool group were formerly lost sight of because of the more pressing needs of infants. No

longer can the preschool period, so important to later adult life, be referred to as the neglected period, since the public health nurse seeks out those children with defects and works for their correction. She is attentive to the nutritional and growth needs of this period and she spreads the good news of diphtheria and smallpox immunization. Perhaps the nurse makes her most important contribution to child welfare when she teaches the mother the elementary principles of habit and character training and helps her to guide the child along the way of wholesome self control and development.

The present economic situation has increased enormously the social problems affecting public health. It is reassuring to realize that so many public health nursing organizations have stood firmly for the principle that dispensing material relief is the function of social workers and not the function of nurses. Coöperation with social agencies to obtain necessary relief for patients has been developed as never before but, considering the pressure, public health nurses have done remarkably little relief giving.

In placing the emphasis on education, care should be taken that the pendulum does not swing too far away from bedside nursing. If we analyze frankly the reason why the nurse has been chosen for so important a part in the public health educational program,

^{*} Abstract of paper read before the Public Health Nursing Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

we must admit that it is because of her nursing and not her teaching ability. Bedside nursing offers the public health nurse her golden opportunity to teach. Educators today are constantly looking for practical projects with which to teach their subjects. The nurse's projects are right at hand when she arranges the toilet-tray, when she rearranges the sick room to allow ventilation without drafts, when she gives the baby a bath, when she disposes of body discharges. It is the most effective method of teaching for lasting results.

In the report of the Committee on Municipal Health Department Practice we find the following:

The question whether the public health nurse should or should not render bedside care has been hotly debated during the past few years. The arguments for purely instructive service rest mainly on two grounds—the administrative difficulties involved in the conduct of private sick nursing by official health agencies, and the danger that the urgent needs of sick nursing may lead to the neglect of preventive educational measures which are of more basic and fundamental significance. On the other hand, the plan of instructive nursing divorced from bedside care suffers from defects which are in reality more serious. In the first place it creates a duplication of effort. There must be a nurse from some other agency employed in the same dis-

trict to give bedside care. Second, the field worker who attempts health education without giving nursing care is by that very fact cut off from the contact which gives the instructive bedside nurse her most important psychological asset. With a given number of nurses per unit of population, we believe that the combined service of teaching and nursing will yield the largest results.

Today, when it is so important to obtain the utmost in value for each dollar spent, a course in fundamental teaching principles, practically applied to public health, if made available to all staff nurses, would probably do more than anything else to increase the effectiveness of home visits.

The nurse is the central figure in the modern public health campaign. However, the nurse cannot stand apart and operate as a unit independent of all others; she must promote friendly, courteous relationships with all the social agencies of the community. There is no individual upon whom the nurse is more dependent, if her work is to be effective, than the health officer. Dr. Geiger of San Francisco stated recently, "The relationship between the health officer and the public health nurse must be founded on mutual trust and respect, and their aims in public health work must be identical."

54th Annual A.W.W.A. Convention in New York

THE coming 54th Annual Convention of the American Water Works Association is to be one of the most instructive, interesting and entertaining conventions yet held.

The meeting will be in New York and there will be present a number of prominent men—consulting engineers, chemists, operators, management and finance authorities.

Reports will be made of the activi-

ties of the National Recovery Committee for Water Works Construction and the part that they have played to date in obtaining allocation of federal funds in excess of \$200,000,000 for the construction of water works and sewage projects and filing of applications for an additional \$660,000,000 for further work.

Members of the A.W.W.A. should remember the dates—June 4 to 8.

CHILD HYGIENE

MATERNAL DEATHS

A Brief Report of a Study Made in 15 States*

RICHARD A. BOLT, M.D., DR.P.H., F.A.P.H.A.

Director, Cleveland Child Health Association, Cleveland, Ohio

SCOPE AND METHOD OF THE STUDY

"The maternal mortality rate in this country is generally recognized as high, and it has shown comparatively slight changes over a period of years. Moreover, information hitherto available concerning maternal deaths consisted only of such limited data with regard to all deaths in a given area as are contained in death and birth certificates and more detailed studies of selected groups. The former were not sufficiently detailed nor the latter sufficiently general to give a picture of the conditions contributing to the 16,000 deaths assigned annually in the United States to causes that are associated with pregnancy and childbirth. At the 1926 conference of state directors in charge of the Maternity and Infancy Act, the chairman of the Children's Bureau obstetric advisory committee presented a plan for a comprehensive study of maternal mortality. It was decided to undertake such a study only in states which were included in the birth registration area and in which both the state board of health and the state medical society made formal request for it. The U. S. Children's Bureau undertook to prepare, with the assistance of its obstetric advisory committee, a schedule for use in all the states studied, and to report the findings. In the preparation of the schedule standards of prenatal care previously set up by the obstetric advisory committee were considered, as were hospital standards and standards of obstetric care in hospitals approved by the American College of Surgeons.

"The material here presented is an abstract of the full report, with tables and careful analyses, of the resulting study made by the U. S. Children's Bureau of all the maternal deaths which occurred in 13 states in 1927 and in these same states and 2 others in

1928. The states in which the study was conducted for both years were Alabama, Kentucky, Maryland, Michigan, Minnesota, Nebraska, New Hampshire, North Dakota, Oregon, Rhode Island, Virginia, Washington, and Wisconsin. California and Oklahoma were included in the 1928 study only. In Michigan, Wisconsin, Minnesota, North Dakota, California, and Oklahoma all or most of the schedules, and in Alabama some of them were taken by physicians on the staffs of the state departments of health. In the remaining states the schedules were taken by physicians on the staff of the Children's Bureau.

"The states of the study are fairly well distributed geographically and fairly typical of the sections in which they are located. The composition of the population for the group of states conforms very closely to that of the entire United States according to the census of 1920.

"In these 15 states, during the years of study, the deaths of 7,537 women were assigned to puerperal causes by the U. S. Bureau of the Census in accordance with the *International List of Causes of Death*. This number of deaths was 26 per cent of the 29,298 deaths from puerperal causes in the entire United States birth registration area for these 2 years. In the states of the study 3,546 (47 per cent) of the maternal deaths were urban and 3,991 (53 per cent) rural; in the birth registration area for these 2 years 54 per cent were urban and 46 per cent rural (rural including towns of less than 10,000). Eighteen per cent of the deaths in this study and 19 per cent of the maternal deaths in the birth registration area were of colored women. Colored women, according to the definition used by the Census Bureau, include Negroes, Japanese, Indians, and Chinese.

"As there were 1,176,603 live births in the states during the years of the study, these 7,537 deaths gave a maternal mortality rate of 64 per 10,000 live births; in the birth

* United States Department of Labor, Children's Bureau Publication No. 221, 1933.

registration area for 1927 and 1928 together the maternal mortality rate was 67. Conditions as regards maternal mortality were evidently better in the states studied. The 4 states admitted to the birth registration area in 1928 all had higher rates than the area as a whole for that year; if they had been in the area in both years of the maternal mortality study the rate for the area for the 2 years would probably have been higher.

"The regions studied, then, are probably fairly representative of the United States as a whole, with some overemphasis on the Pacific Coast and North Central States, and some underemphasis on the Rocky Mountain regions, the far South, and the eastern industrial centers. Conditions as regards maternal mortality were apparently better in the regions studied—they were certainly not worse—than those obtaining in the United States as a whole.

"The collection of data was begun in February, 1927, and most of the schedules were completed before July 1, 1929. All the finished schedules were sent to the Children's Bureau for statistical examination, and tabulations were made there. A very close contact between the interviewers and the Bureau was maintained in order to keep the interpretation of the schedules uniform.

"The routine used was as follows: All certificates of deaths assigned to puerperal causes as reported to the state departments of health were copied. Birth certificates were matched when possible. The physicians or other persons signing the death certificates were then interviewed. The families were not visited, except where there were no physicians. The hospitals and clinics in which the patients had received care were visited, and the case records were studied with the consent of the attending physician. In some cases in which the interview was delayed the physician had forgotten many of the details of the case. Very few of the physicians kept case histories, and usually no laboratory work other than a urinalysis and a blood pressure examination had been done. However, most of them remembered the cases vividly. The physicians interviewed cooperated most heartily, giving freely of their time and helping in every possible way."

RECOMMENDATIONS BY ADVISORY COMMITTEE

"Maternal deaths are due in large part to controllable causes. But how is control of these causes to be established? First, the medical profession and the public must know the facts, and then each group should take appropriate and decisive action. Physicians

have the responsibility for leadership in both the medical and the community program for such control. As the facts become more widely known, others will assume this leadership if they do not.

"Recommendations for action looking to prevention of maternal deaths are addressed to the medical profession and to the general public.

TO THE MEDICAL PROFESSION

"A. Physicians must assume the leadership in the field of maternal care by:

1. Informing the public that the high mortality during pregnancy, delivery, and the postpartum period is due largely to controllable causes.

2. Recognizing that every mother must have adequate prenatal, delivery, and postpartum care.

3. Instructing the public as to what constitutes adequate maternal care.

4. So organizing the available resources of their communities that every mother can receive adequate maternal care.

5. Warning the public as to the dangers occasioned by abortions, spontaneous or induced.

"B. In order that more accurate information may be secured relative to cause and prevention of maternal deaths:

1. Physicians should make a greater effort to study by autopsy and other scientific means every maternal and fetal death, for in many cases this is the only means of ascertaining the true cause of death.

2. Physicians are urged to exercise the greatest possible care in making out maternal and fetal death certificates, so that vital statistics may be more accurate and therefore more valuable.

3. Bureaus of vital statistics are urged to query maternal and fetal death certificates recording an indefinite cause of death; for example, 'Caesarean section' alone.

4. Medical societies and departments of health in cooperation should investigate each maternal death within a few weeks of the death.

"C. In order that physicians in general may have a better understanding of the fundamentals of obstetric care:

1. There should be larger and better facilities for clinical training in obstetrics.

2. Undergraduate students should have a much wider contact with obstetric patients.

3. The state medical societies, the medical schools, and state departments of health should provide or arrange for postgraduate

teaching in the various counties in order to keep the local practitioner in touch with the best obstetric thought and practice.

"D. It is recommended that all physicians practising obstetrics give particular consideration to:

1. The importance of good aseptic technic, including the use of rubber gloves and masks that cover nose and mouth
2. The dangers to mothers from carriers of infection
3. The dangers of the use of pituitrin during labor
4. The dangers of multiple, forcible, and radical procedures in obstetrics
5. The proper indications and contraindications for various obstetric operations, especially (a) the dangers of major operations in the presence of shock and hemorrhage, and (b) the dangers of Caesarean section after vaginal manipulations or long labor
6. The proper selection of anesthetics
7. The value of blood transfusions
8. The dangers of intrauterine manipulation in cases of infected abortion
9. The dangers of abortion or delivery to women suffering from acute diseases, especially infectious diseases
10. Knowledge of the symptoms of some of the less common but more serious complications of delivery such as rupture of the uterus

"E. It is recommended that state medical societies working in coöperation with the state departments of health consider the development of some plan by which well trained regional obstetric consultants may be made available.

TO THE GENERAL PUBLIC

"There should be widespread education of the public as to the following:

1. That the high maternal death rate is due largely to controllable causes.

2. That it is necessary for all women to have adequate supervision and medical care during pregnancy, labor, and the postpartum period, such supervision and care to begin early in pregnancy and to be continuous through the postpartum period—

a. In order to safeguard the health of both mother and child.

b. In order especially to control the infections, toxemias, and hemorrhages that this study and others have shown to be real menaces to life.

3. That there is danger of death or serious invalidism following abortions, spontaneous or induced.

4. That the community has a definite responsibility to provide adequate medical and nursing facilities for the care of women during pregnancy, labor, and the postpartum period. This predicates the proper organization of hospitals, outpatient services, and medical and nursing personnel and applies to both home and hospital care. The community should know the standards for hospitals taking obstetric cases that have been drawn up by the American College of Surgeons.

5. That judicious selection of the hospital to be used for maternity care is of the greatest importance when hospitalization is planned.

6. That the better education of those caring for women during this period is essential and should have public support. This includes adequate obstetric training for medical students, postgraduate obstetric training for physicians in practice, to keep them abreast of modern developments, the training of nurses in good maternity care, and the training and supervision of midwives in communities where midwives still practise.

7. That it is important to make careful and intelligent selection of the attendant for maternal care."

SCHOOL EXCLUSIONS FOR GONORRHEAL INFECTIONS IN WASHINGTON, D. C.

THE following is quoted from an article by Ella Oppenheimer, M.D., and Ray H. Everett (*J. Soc. Hyg.* 20, 3:129-138 [Mar.], 1934):

Because many individuals and organizations in Washington, interested in children and in the control of venereal diseases, felt that some provision should be made for the education

of children who apparently were excluded from school for relatively long periods of time due to venereal disease, a limited (April-June, 1932) study* was undertaken by the U. S. Children's Bureau and the Social Hygiene Society of the District of Columbia. Its

* This work and detailed report thereon, Anna Ruth Medall.

aims were to determine the facts regarding the probable numbers of such children, the period of their exclusion from school, aspects of their social and economic background and of their treatment and treatment facilities in Washington which had a bearing on the problem. Because an individual with syphilis is rendered non-infectious from the point of view of ordinary social relationships after a few treatments, the study was limited to venereal disease of gonorrheal or presumably gonorrheal origin.

The study was made possible by the coöperation of the Health Department, the Attendance Department of the Board of Education, the Children's Hospital, the Board of Public Welfare, the Juvenile Court and other agencies. This report presents a summary and brief comments on the conditions found.

SUMMARY OF FINDINGS

1. A total of 321 school children, 259 girls (210 colored and 49 white) and 62 boys (55 colored and 7 white) were found listed by the four agencies whose records were studied, as having either a definite or suspicious gonococci infection. (The 321 individual children involved 537 records, 159 being recorded by one agency only, 110 by two, 50 by three and 2 by four agencies.)

The ages of these 321 individual children ranged from a small number under 6 years to one 21 years of age. Most of them were of compulsory school age (7-15 inclusive). All under 7 years of age, and 16 and over, had actual records of school exclusion. The predominance of girls, and of the colored is evident. Sixty-five per cent of the individuals whose records were studied were colored girls, approximately half of whom were adolescent. Among the white there were few in the adolescent group.

2. The data gathered indicated that the extent of school exclusions because of gonococcal infection among children in the District was not as great as had been indicated in a previous report. Although the range of exclusion periods was great, large numbers of children whose exclusions appeared on the records to have been greatly prolonged were at institutions where full- or part-time school work was available. This does not minimize the undesirable consequences to the child with a school exclusion of several months. The period of exclusion tended to greater length in the adolescent age groups.

3. Considerable evidence was gathered of faulty reporting to the Department of Health. Approximately 35 per cent of the total 321 children listed by the four agencies whose

records were studied, were not registered for exclusion by the Department of Health.

4. It was found that very few children were actually out of school during the entire period of their official exclusion; also that some children who had been authorized to return to school were still out of school.

5. Children were found excluded from school but not under regular medical supervision and treatment because of failure of parents to understand the need for it, economic and social conditions, and inadequate social service follow-up.

6. Information available at various agencies on individual children who were also visited in their homes indicated a woeful lack of exchange of accurate information in regard to the child's condition among the various interested agencies. Incorrect and frequently distorted statements regarding the venereal diseases were frequently noted in social case records.

RECOMMENDATIONS

1. Reporting to the Department of Health by all clinics, hospitals, and physicians treating these cases should be stimulated.

2. Provision should be made for adequate check-up in regard to school attendance of all cases officially excluded from school, and also for adequate medical supervision of these children. Responsibility for the former would seem logically to rest with the Attendance Department, responsibility for the latter would seem to rest with the Health Department.

Whatever measures are mutually agreed on by these two public agencies should assure such record-keeping, medical treatment and follow-up as will guard both the health and educational rights of the child. Absolute lines of demarcation between the duties of the two departments cannot be laid down here. Responsibilities should be assumed on the basis of functional objectives. For instance, it seems logical that continuance of medical treatment should be a responsibility of the Health Department and this involves such follow-up as may be necessary to assure an adequate continuity of treatment. Similarly continuance of education is the concern of the Department of Education. The community may fairly charge this department with the duty of checking up on exclusions and keeping in touch with every case so that the exclusion period may be made as brief as possible.

3. Provision should be made for the instruction of those children within the compulsory school attendance age who are ex-

cluded from school and are not in institutions.

4. It should be recognized that this problem of children, largely girls, who are excluded from school because of gonococcic infection has two aspects, first that of the young child, and second, that of the adolescent individual whose infection frequently has been due to sexual relations. The special needs—both social and medical—of each group should be met.

Neglect both of health teaching and sex education in school and home, together with lack of wholesome recreation facilities are responsible for many infections in the adolescent group. The school and health department workers responsible for dealing with these children should be qualified to aid them to a better understanding of sex problems. The provision of better recreational facilities

is a community responsibility in which both public and private agencies should take a part.

The occurrence of the infection in the young child indicates, as has been repeatedly emphasized in the past, the importance of further careful studies on the epidemiology of gonorrheal infections.

5. A series of lectures should be arranged for social workers, and others, covering the social and medical aspects of the venereal diseases in children. (The Social Hygiene Society has already planned such an institute for the District of Columbia.)

6. The desirability of further scientific research on the whole subject of gonorrheal infection and its treatment is indicated by this study as by many others. Every effort should be made to make such research possible.

INDUSTRIAL HYGIENE

Medical Study Trip to Hungary
—At the invitation of the Hungarian Medical Postgraduate Committee of Budapest, an American Committee has been organized to promote a medical study trip to Hungary, August 18–Sept. 28, 1934, headquarters St. Gellert Hotel, Budapest. The American Committee consists of Dr. Ervin Torok, Chairman, and Dr. Richard Kovacs, Secretary (1100 Park Avenue, New York, N. Y.). It is proposed not to have “1 and 2 night stands,” while en route, but to spend most of the time in Hungary with, however, 5 days’ stay in Munich and an opportunity to attend the Passion Play at Oberammergau. Archduke Dr. Joseph Francis, President of the Budapest Medical Association, assures that everything will be done to make the stay in Budapest most successful not only from a scientific but also from a social point of view.

13th Annual Report, Industrial Health Research Board—This is for the year ending June 30, 1933. The investigations have covered (1) En-

vironmental conditions—lighting, noise, vibration, dust, the physiology of heating and ventilation; (2) the physiology and psychology of work; (3) sickness and absenteeism; and (4) vocational suitability.

An investigation was made of the effects of vibration on workers using vibrating tools and machinery. It was found that marked chilling of the fingers followed vibration, and that the recovery of the circulation in the fingers was definitely delayed. During vibration the increased air movement caused an increased cooling power, but the physiological effects were greater than could be accounted for by this circumstance. It was also found that the hands of such workers showed an increased susceptibility to cold. The fingers also developed cyanosis on immersion in water between 59° and 68° F. which was not the case with the normal hand. The wearing of gloves did not prevent these phenomena. Such vibrations did not appear to increase metabolism nor to affect the pulse rate.

In the spinning section of the cotton industry, the dust and cotton fiber is

productive of an excessive amount of respiratory disease. Professor Maitland in Manchester found that histamine may be present. This gives a clue to the irritant causing "card-room asthma" which may in turn lead to possible "desensitizing" of susceptible individuals.

Much work was done with precision instruments in determining warmth and comfort as with the eupatheoscope, the kata-thermometer, and the globe thermometer. There are many other interesting summaries in this Report.—H. M. Stationery Office, 1933, 36 pp., price 9d. net (procurable from the British Library of Information, 270 Madison Avenue, New York, N. Y.).

Occupation and Health—Brochures Nos. 324–332 (rice-field workers, road makers, scavengers, silicon, silk, skin, social welfare, soldering, soot, and sport), and Nos. 333–344 (strontium, cinema studios, submarines, sumac, syphilis, talc, taxidermists, temperatures, tetanus, textiles, thallium, thorium, tobacco, and toluene) have now appeared in this series of monographs from the International Labour Office. It is stated that the series is complete through the letter "S." Obtainable from L. Magnusson, U. S. Branch, Jackson Place, Washington, D. C.

Occupational Disease Summary, New York, 1933—A report from Director J. D. Hackett of the State Division of Industrial Hygiene (80 Centre Street, New York, N. Y.) shows that a total of 866 occupational diseases were reported for the year 1933 as compared with 610 the previous year. The outstanding difference occurred in respect to reports of poison ivy which increased from 30 in 1932 to 131 in 1933.

The leading afflictions reported in 1933 were due to amido-benzol com-

pounds 33; calcium hydroxide 15; carbon monoxide 30; cement 16; chrome 22; dermatitis, non-occupational 40, occupational 50, and unknown 13; diseases not specified 28; dyes (furs 22, leather 2, silk 2, not specified 7), total 31; friction 30; hydrogen sulphide 10; lead (various forms) 82; poison ivy 131; soap 27; soap powder 39; sodium carbonate 11; sodium hydroxide 13. A rather large number of scattered causes contributed up to 10 reports each.

A considerable increase of dermatitis reports over the year 1932 was mainly due to the enlargement of the scope of the Compensation Act.

It still remains a fact that about half the scheduled poisons and diseases of the New York State Workmen's Compensation Act are practically inoperative. There were no cases under seven of the headings and only one or two cases at maximum in seven more; that is to say, out of 27 of the scheduled poisons, about half, only, mean protection for the worker.

Occupational Disease and Compensation—This is a closely knit summary of occupational diseases reported in New York State during the year 1933, Part I being included in this issue, and pertaining to claims classified according to the decision of the referee, to the number of hearings and disposition of cases, to the length of disability and disposition of cases, and to the alleged causative agent and disposition of cases. The total cases considered was 692, of which 283 were disallowed, 250 given awards, and 154 were pending at the end of the year. Part II will consider the diagnoses and occupations of claimants.—Division of Women in Industry, *Indust. Bull.*, New York Department of Labor, Albany, 13. 2:37–39, 42 (Feb.), 1934.

Occupational Disease Summary, Ohio, 1933—The Bureau of Occupational Diseases, State Department of

Health, reports (Sect. 1243-1) a total of 1,258 occupational diseases in 1933 as compared with 1,159 in 1932. These gross figures are practically the same as for each of the preceding 5 years.

Of the 21 afflictions which are *compensable* under the Ohio law (Sect. 1465-68a), only 16 registered reports. Of these, dermatitis (variously specified) comprised 726, tenosynovitis 191, lead poisoning (and lead absorption) 134, chrome ulceration (nasal or skin) 20, prepatellar bursitis 19, brass or zinc poisoning 12; volatile petroleum products 9, potassium cyanide poisoning 5, benzol poisoning 3, compressed air illness 3, sulphur dioxide poisoning 2, and 1 each of the following: phosphorus, arsenic, carbon bisulphide, tar epithelioma and carbon dioxide,—total 1,129. In addition, 104 *non-compensable* occupational diseases were reported where the causative agent was specified, and 25 where only the nature of the affliction (as bronchitis, tuberculosis, etc.) was stated. Chief among the non-compensable diseases were those due to dust inhalation, total 47, principally silicosis. Copper-sodium cyanide also comprised 23 in this group.

Of the 1,258 occupational diseases, 300 occurred through inhaling the substance, 732 by way of the skin, 202 through strain, and 23 through friction.

Acute mishaps, even though due to poisons, sudden strains, etc., are not included in the above figures.

Lead poisoning occurred in various industries: storage batteries 51; paints, dry colors, and painting 15; lead manufacture or recovery 14; automobiles 8; printing and publishing 8; caskets and vaults 5; pottery 4; sanitary ware 4; rubber 3; and the balance scattered. Approximately half of the lead poisoning cases were considered to be no more than lead absorption. Only one female worker (tile scraper) was involved.

Of the 732 total cases of *dermatitis*, 142 occurred among females. The lead-

ing causes of dermatitis were exposures to alkalis and cleansers 47, bakelite 22, gasoline 39, chromium compounds 24, dyes and dyed goods 42, lime and cement 33, oils and cutting compounds 109, paints, enamels, etc. 15, fungi, etc. 21, plants, woods, etc. 28, plating solution 18, rubber 39, and textiles (probably dyed) 24. Females led in leather, textiles and fungi, etc., and practically equalled males in solvent cements and dyed goods.

From the date of the receipt of the first reports, May, 1913, a total of 15,887 occupational diseases have been reported to and including December 31, 1933. During the first 8 years, before occupational diseases became compensable, only 2,575 or an average of 322 cases per year were reported. Since compensation began (August 4, 1921), 13,312 have been reported, or an average of 1,065 per year.

Occupation Hazards and Diagnostic Signs—This guide to impairments to be looked for in hazardous occupations is a revision of former *Bulletin No. 306*, published in 1922. The material has been considerably extended with inclusion of much new information in particular on radiant energy, but also on the risk of 94 poisons as respects their industrial occurrence with a brief line or two for each in regard to symptoms and what to look for. There are also covered (A) Abnormalities of temperature and humidity, (B) Compressed air, (C) Dampness, (D) Defective illumination, (E) Dust, (F) Infections, and (H) Repeated motion, pressure, shock, etc. The symptoms, conditions or diseases cited are those which are reported in the best works available on the several hazards. There has been a complete revision of the method of presenting some of the hazards, although the number of hazard groups remains the same. The number of hazardous occupations

has been increased to approximately 900. There are 9 pages devoted to the alphabetical list of hazardous occupations, each of which is cross-referenced to a list of hazards, etc. While the works of many have been consulted, the authors acknowledge especial indebtedness to Dr. A. J. Lanza and Dr. William J. McConnell.—Louis I. Dublin and Robert J. Vane (Met. Life Ins. Co.), *Bulletin 582*, U. S. Bureau of Labor Statistics, 1933, 52 pp.

Report to the General Court of the Special Industrial Disease Commission, Massachusetts—This Report of 215 pages issued under date of February, 1934, is obtainable from the Division of Occupational Hygiene, Department of Labor and Industries, State House, Boston. It followed upon the Acts and Resolves of 1933, approved by the Governor, July 12, 1933, which provided for investigation of certain questions relative to the granite and foundry industries and of the problem of industrial disease compensation generally.

Part I is devoted to working conditions found as a result of surveys of these two industries, Part II of such working conditions on the health of workers particularly as regards silicosis with some study of mortality rates. Silicosis was found in a representative group of granite workers to the extent of 15.2 per cent, and silicosis with tuberculosis, 7.6 per cent. Positive correlation was found between the duration of the exposure and dust concentration. Tuberculosis deaths were one-third of all deaths of granite workers. Silicosis was found in 8.8 per cent of a representative group of foundry workers and silicosis complicated by tuberculosis in 2.6 per cent. Pneumonia was the final cause of death in about one-fourth of all the foundrymen. One section is devoted to silicosis compensation statistics. Petro-

graphic determinations including the sericite content of a number of granite and foundry dusts showed same to be very rare in Milford and Westford granite, present to the extent of about 30 per cent of the finer material in Fitchburg and to about 10 per cent in Quincy granite. In foundry dusts, usually little or no sericite was found, but in some instances, as many as 20 particles of sericite were found to 100 particles of dust, and 45 particles in dust from an enamel spray booth (considering only particles less than 10 microns in diameter).

Part III considers means of lessening dust exposure, and Part IV, legislative and administrative aspects of the problem. In the latter, a summary is given of laws in other states and countries followed by a discussion of the Massachusetts situation and a brief mention of the Taunton case where, in April, 1933, some 42 foundrymen were summarily discharged, following physical examinations by a local physician at the behest of an insurance company, on the theory that they were suffering from silicosis or tuberculosis. The Commission finally secured a total payment of over \$17,000 for payment of compensation for the entire time they were out of work and the Commissioner of Public Health found that 41 were fit to return to work which they did.

A most important part of the report is the recommendations (pages 181-189) which should be read in full by those interested. They can also be secured in a separate mimeograph form. Briefly, they cover definitions, preventive regulations, certificate of compliance with regulations, employers must provide insurance, insurers must carry certificated risks, entrance physical examinations, annual physical examinations, compensation for pulmonary disability restricted, all persons exposed subject to preventive regulation, physicians' reports paid for and

privileged, schedule and experience rating for occupational disease risks, cancellation of policies restricted, the creation of a Division of Occupational Hygiene in the Department of Labor and Industry (with a personnel having special knowledge of the causes and prevention of occupational diseases and sufficient to make the required investigations and evaluate hazards in co-operation with the Department of Public Health so as to promote occupational health and safety education), the addition to the personnel of the Division of Adult Hygiene of the Department of Public Health of an occupational medical staff with such assistance and facilities as necessary to efficient performance, the creation of a Medical Board of Review composed of three physicians (a clinical pathologist, a roentgenologist and a chest disease specialist), and arrangements for statistical data to be collected by the Department of Industrial Accidents. Various legislative drafts (Massachusetts) complete the Report.

A Test of the Capacity of the Nose to Collect Dust—Dr. Gunther Lehmann of the Emperor William Institute for the Physiology of Work has worked out a method to determine what percentage of the inspired dust can be retained by the nose. With this method, dust-laden air is blown into the nose, and the air, while the breath is being held, emerges from the mouth. By means of two konometers, the concentration of the dust is measured before it enters the nose and after it emerges from the mouth. It was found that many noses retain up to 75 per cent of the inspired dust, whereas others allow virtually all the dust to pass out. The concentration of the dust plays a small part; likewise the velocity of the air in motion, and the chemical nature of the dust. The observations made it seem that persons with poor dust fixation

capacity of the nose are particularly disposed to pneumoconiosis. Therefore 89 stone cutters who had worked in stone from 10 to 30 years were examined. Of this number 53 were healthy, while 36 had pneumoconiosis. The dust fixation capacity of the healthy workmen averaged about 52.3 per cent, while the average of the workmen with pneumoconiosis was about 22.3 per cent. Of the 46 stone cutters with a dust fixation capacity above 40 per cent, only 2 presented pneumoconiosis, while 44 were exempt. Of the stone cutters with a dust fixation between 29 and 40 per cent, 5 were ill and 5 were healthy, while 2 were showing just the first symptoms of disease. Of the 31 stone cutters with a dust fixation capacity under 29 per cent, only 2 were healthy, while all the others were affected with pneumoconiosis. A good dust fixation capacity of the nose affords therefore almost complete protection against pneumoconiosis, whereas persons with poor dust fixation capacity, under corresponding conditions, are almost certain to develop pneumoconiosis. Applicants for work as stone cutters should be given this test, and those with poor dust fixation capacity should not be allowed to work where a menace of silicosis exists.—*J.A.M.A.*, 102, 6:471 (Feb. 10), 1934.

The Physiological Response of the Peritoneal Tissue to Dusts Introduced as Foreign Bodies—This is a report of an important investigation having a bearing on pneumoconiosis. Summary.

1. A definite quantity (0.2 g.) of dust in suspension was injected intraperitoneally into guinea pigs.

2. Dusts of 2 particle-size groups were used—one of the screened material with particles less than 43 microns (325 mesh), and the other of air-separated material with particles varying from less than 2 to 8 microns in size.

3. The animals injected with the coarser material were examined 7, 14, 30, 56, and 112

days after injection, and those treated with air-separated material were examined after 7, 14, 30, 56, and 90 days.

4. The response caused by the dust in the peritoneal cavity was constant in all of the animals injected with an individual dust and could be classified as an absorption, proliferative, or inert reaction.

5. In the absorption reaction the injected dust disappeared from the peritoneal cavity without the production of scar tissue.

6. In the proliferative reaction the nodules produced by the dust continued to increase in size up to 112 days after injection, the maximum duration of the tests in this series.

7. In the inert reaction the amount of injected dust remained approximately the same in the peritoneal cavity throughout the various periods, but the nodules became more flattened and fine particles of dust were carried over rather extensive areas in the peritoneum by phagocytes.

8. Calcite, limestone, precipitated calcium carbonate, gypsum, and cement exhibited an absorption reaction.

9. Quartz, chat, and flint produced a proliferative reaction.

10. Soapstone, carborundum, jeweler's rouge, anthracite coal, bituminous coal, and precipitator ash were inert in reaction.

It is concluded that the peritoneal response to injected dust is of such character that it may be used as a basis for the classification of industrial dusts from a physiological standpoint. Tests of longer duration are now in progress to determine the ultimate fate of the dust in the peritoneal cavity. However, 90 days appears to be a sufficient time.—John W. Miller and R. R. Sayers, *Pub. Health Rep.*, 49, 3:80-89 (Jan. 19), 1934, illustrated.

Gas Hazards in Sewers and Sewage-Treatment Plants — These hazards are those due to inflammable and poisonous gases and to oxygen deficiency. The first two mentioned are derived from volatile liquids, leakage from gas mains, or the products of fermentation of sewage. Digestion tanks show chiefly CH_4 (70 to 85 per cent), CO_2 (10 to 20 per cent), and occasionally nitrogen and a trace of hydrogen. Septic tanks have

shown CH_4 (75-79 per cent), CO_2 (3.4-6 per cent), nitrogen (about 17 per cent), and occasionally traces of other gases. Imhoff tanks have shown CH_4 (80 to 85 per cent), CO_2 (7 to 20 per cent), and more or less nitrogen. None of the above gases are poisonous *per se*. Methane, of course, is both inflammable and explosive.

A considerable range of poisonous and explosive gases have been found in manholes, depending upon the character of discharges into sewers. The chief characteristics of some of these are given—ammonia, benzol, carbon dioxide, ethane, methane, gasoline, hydrogen sulphide, sulphur dioxide, and carbon monoxide.

Among precautions especially to be taken before entering manholes are those laid down by the National Electrical Safety Code: Never enter—

until you have assured yourself that it is free from dangerous gases, by testing with an approved safety lamp, by ventilation, or by other adequate methods.

The simpler tests are described. The absence of odors is no indication of safety. Great precautions should be taken to detect deficiency in oxygen as by the use of small animals, especially birds, but also by precision instruments. Hose masks and canister masks should also be at hand. The essential steps in resuscitation should be known (described). A bibliography accompanies.

The paper is reviewed by Emery R. Hayhurst, who recited some personal investigations he had made in connection with 4 sudden deaths in a silo (*J.A.M.A.*, Oct. 31, 1914, p. 1570) and 4 other sudden deaths in a vertical caisson (*A.J.P.H.*, Oct., 1925, p. 924). These last were practically duplicated in the Thames River catastrophe (*J. Indust. Hyg.*, Oct., 1932, p. 291). The various air analyses are given in connection with each of these 3 mishaps. The great regret is that rescuers so often lose their lives. Indeed, cases are on

record where the rescuer, evidently through his straining efforts, has lost his life while the victim, having been rendered unconscious and therefore breathing lightly, has been rescued and revived. Therefore the rescuer should proceed most cautiously, keeping in mind other help, a respirator, rope or cable, and above all, the necessity of stirring up the gaseous mixture so as to get fresh air down to the victim as well as for his own use. Thus stirring up the gaseous condition may be more effective than direct rescue. The point is to get fresh air to the victim the quickest way possible.

The principal paper is by Dr. R. R. Sayers.—*6th Ann. Rep.*, Ohio Conference on Sewage Treatment, Oct. 13-14, 1932, pp. 11-20 (Ohio Department of Health, Columbus), published March, 1934.

The Histopathology of Methyl Alcohol Poisoning—This study was made on 41 monkeys, 36 rabbits, and 81 rats. The alcohol was administered by inhalation, by skin absorption, and orally. The method of application made no apparent difference either in the type of lesions or in their severity. There was some variation in species, however, in regard to susceptibility—rats being the most and rabbits the least susceptible. Individual variations in susceptibility were also very marked.

The characteristic lesions of methyl alcohol poison are degenerative ones. Only the parenchymal tissues and neurons are affected. This granular degeneration may proceed to necrosis. There is practically never injury to connective tissue and therefore seldom any fibrosis. These changes are accompanied by a generalized capillary engorgement and edema. The pathological conditions in the eye are identical with those found elsewhere in the body. The edema is most marked in the retina and optic disc. Degeneration of the gan-

glion cells of the retina is sometimes followed by degenerative changes and fibrosis within the optic nerve. There may be multiple degenerations involving nerves other than the optic nerve.

Enlargement of the lymph nodes and the spleen was frequently found, a phase which it is planned to investigate further. Remarkable recoveries of blind animals, rendered so by the alcohol, were encountered even during the continued administration of the methyl alcohol. A considerable bibliography accompanies.—Ernest Scott, Mary K. Helz and Carey P. McCord, *Am. J. Clin. Path.*, 3, 4:311-319 (July), 1933.

Industry Reports—

Marble, Limestone, and Granite—December, 1933, VIII, 12:123-136

Insecticides and Spraying Operations—January, 1934, IX, 1:1-18

Glass Bottle Manufacturing—February, 1934, IX, 2:19-26

Cooperage—March, 1934, IX, 3:27-34

Each of these reports considers the extent and scope of the industry, conditions in typical plants, an exact description of the various manufacturing processes, the potential health-hazards, and a classification and index of jobs.—N. W. Pettys, Editor, Retail Credit Company, Atlanta, Ga.

Industrial Diseases in Denmark—

An investigation was made of the incidence of silicosis in various industries, beginning with the china industry which employs about 1,400 persons (to be published). An inquiry of 80 persons having 3 or more years' service with quartz-bearing stone showed silicosis in a marked degree in about 50 per cent, and these persons had about twice as many days of sick leave for respiratory ailments as the other workers, and 4 times as high as among workers in other occupational groups.

A new disease attributed to fluorite (cryolite) affected the structure of the

bones consisting in a thickening of the distal part and an ossification of the ligaments and muscles. The workers complained of pains similar to those of gout and showed a decrease in mobility of the limbs. They also had nausea, loss of appetite and vomiting. One woman who had worked under such exposure during several pregnancies had had children whose bones were not affected.—*Indust. & Labour Inf.*, XLVIII, 3:69-71 (Oct. 16), 1933.

Sickness Among Male Industrial Employees During the Final Quarter of 1933—The incidence rate of cases of illness causing disability for 3 consecutive days or longer among 154,000 male industrial employees was lower than in the corresponding period of any 1 of the 4 preceding years. This was due principally to a decrease in the non-respiratory diseases—a new departure since this is the first time that such diseases have decreased enough to lower appreciably the rate of total sickness. The 4th quarter rate for these afflictions was 37.5 per 1,000 men per year as compared with an average or expected rate of about 46.0 for the period. The reporting companies or sick benefit associations cover all parts of the country, but most of them are located in the North Central and North Atlantic States.—Dean K. Brundage, U. S. Public Health Service, B-409, 1934, 3 pp., mimeo.

Silicosis in Rochester—This discusses a deluge of common lawsuits for negligence falling upon various industrial employers in Rochester. These involve particularly silicosis, pneumoconiosis, and fibrosis of the lungs.—William S. McCann. *Bull. No. 82*, The Self Insurers Assoc., New York (466 Lexington Ave.), Jan. 2, 1934. 3½ pp.

Occupational Diseases: What It Means to Employers and the Ad-

ministrators of the Law—This is an article by Hon. Henry D. Sayer, Former Industrial Commissioner, and follows the above article by Dr. McCann (pp. 4-6).

Report of Conference Committee of Five in re Occupational Disease—Opinions and experience with the all-inclusive coverage of occupational diseases under a compensation law is reviewed. Such will breed speculative and wasteful litigation, create doubts and uncertainties and thereby needlessly increase the burden upon industry. Hence the present New York specific schedule plan is more reliable. If silicosis under proper safeguards and perhaps asbestosis were added, the New York statute would then be recognizing all important diseases known to arise from employment without making the law a general statute for "Health Insurance." The chief concern should be to make a risk "insurable," to insure *unknown* risks cannot be safely undertaken.

The creation of a medical board is regarded as essential. Special provisions should be made for silicosis and possibly asbestosis, but with proper safeguards and limitations. These afflictions should be divided into stages, as is done elsewhere, and compensation adjusted accordingly. The Act should not be retroactive. The employees should be obligated to certain regulations (1) for the prevention of silicosis, (2) periodical and medical examinations, and (3) the furnishing to employers, upon request, substantially accurate statements of previous employments and illnesses, during, say, 6 years immediately preceding.

The article continues with, "Which employer shall pay?" "Problems relating to cost," and "A special supplemental act desirable."—Compensation Insurance Rating Board, Jan. 11, 1934, 13 pp., mimeo. Association of Casualty

& Surety Executives, 1 Park Ave., New York.

Child Labor: Facts and Figures—About 50 codes under the N I R A had been approved by the President when this bulletin went to press (November 10, 1933). The subject matter covers:

(1) Child labor in the United States—boys and girls, 10 to 17 years of age, who in 1930 were gainfully employed to the number of 2,145,919, about one-third of whom were under 16 years of age, and more than 10 per cent under 14. Agricultural pursuits engaged 70 per cent between 10 and 16 years of age. However, there was a total drop between 1910 and 1930 in the proportion of children of this age group in agricultural occupations of 75 per cent.

Outside of agriculture, that is, in commerce, manufacturing, transportation, clerical and domestic work, etc., the proportion showed a decrease of 37 per cent from 1910 to 1920 and a greater decrease (58 per cent) from 1920 to 1930. At the present time workers 10 to 17 years of age, inclusive, constitute 4.4 per cent of all those gainfully occupied. Children under 16 constitute 4.5 per cent of all agricultural workers, 0.5 per cent of those in manufacturing, 0.4 per cent of clerical workers, 1 per cent of those in domestic and personal service.

(2) Children's work and working conditions.

(3) Legal regulations of child labor.

(4) A brief history of child labor comprises the rest of the Report, including tables in the Appendix.

Regulation is most common in manufacturing and in the extraction of minerals, followed next by stores and other business places. On the other hand, agriculture, domestic service and street trades are subject to little, if any, regulation. The present needs are: (1) to make the laws more comprehensive, (2)

to raise the minimum age standard, (3) to raise the age to which regulations apply, (4) to revise downward the maximum hours permitted, (5) to extend to minors increased protection against occupational hazards, (6) to improve administrative machinery, and (7) to coördinate better child labor and school attendance laws.—U. S. Children's Bureau, *Pub. No. 197*, 85 pp.

Workmen's Compensation for Occupational Diseases—This volume is stated to be a partial revision of the convention concerning workmen's compensation for occupational diseases, and the 5th item on the agenda for the 18th Session of the International Labour Conference to be held in Geneva in 1934. The subject matter is handled in 4 parts: (1) Compensation for occupational diseases—definition, distinguishing features, principles of legislation now in force, scope, medical coöperation in insurance, various insurance relations, statistics, and cost; (2) compensation for occupational diseases in various countries with a summary of legislation in table form (pp. 57–201); (3) silicosis—definition, physiopathology, statistics, symptomatology of the three stages, complications, diagnosis, prognosis, medico-legal aspects, cost of compensation, and bibliography (pp. 203–253); and (4) silicosis legislation—especially that related to various British possessions, but also an analytical table covering all countries (pp. 257–314). The conclusions pertain to the revision proposed (A) for including a certain number of occupational diseases comprising silicosis and (B) a rather complete substitution for 8 articles, having to do with the method of ratification by the different countries, and providing for revisions from time to time. The volume which comprises 328 pages is indexed. Part I also contains appendices concerning definitions and periodic examinations in unhealthy trades. Ob-

tainable from L. Magnusson, U. S. Branch, International Labour Office, Jackson Place, Washington, D. C., price \$1.50.

Pollution of the Air by Smoke—The author briefly reviews the history of the investigation of atmospheric pollution of which he has been superintendent of observations under the governmental Department of Scientific and Industrial Research for a number of years. The idea had its birth in London in 1911. The organization now has the coöperation of about 40 bodies, chiefly municipal authorities, and the maintenance of from 90 to 100 stations, which send their monthly deposit results to the author's office for compilation. Interest has continued to increase year by year.

The author, who is a physician, feels that the ciliated linings of the air passages of human beings, especially those who suffer from bronchial diseases, are injuriously affected by the suspended soot which contains tar and sulphur acids. Particularly men who have to work the hardest are the worst sufferers, since they are compelled to breathe more deeply than sedentary workers. In 1922 the author demonstrated (*Dust in Expired Air, Transactions* made by the Medical Society of London, Vol. XLV, 1922) that a fair proportion of suspended matter inhaled actually passes to the depths of the lungs. There are also to be considered the evil effects of cutting off daylight, sunshine and ultraviolet radiation, and the indirect effect due to the production of fogs.

Present condition shows that there was a steady improvement in the atmospheric picture of London and Glasgow until about 1921-1922, but since that date, very little if any improvement. There are many worse offenders than London and Glasgow. More drastic methods are required for dealing with pollution from factory chimneys, also

domestic fires. During the current year (1932) a general improvement was noted, the deposit of tar being 80 per cent, and the total solids being 86 per cent of the general average of the preceding 5 years. Apparently sulphur acids are most concentrated when smoke forms fog.—J. S. Owens, *J. State Med.*, 42, 1:51-58 (Jan.), 1934.

Facts on Disease of the Coronary Arteries, Based on a Survey of the Clinical and Pathologic Records of 762 Cases—Only "the incidence in relation to occupation"—a single paragraph—is excerpted from this paper:

Those who emphasize the rôle of the strain of 20th century existence in causing coronary disease, call attention to the numbers of business executives with great responsibilities who succumb to its ravages. Our figures do not lend support to this point of view (Table 7). The largest percentage of coronary cases was found among foremen and skilled workers, i.e., 44.2 per cent of the total autopsies in this occupational group showed coronary disease. The professional and executive group came second (39 per cent). Next in order of frequency came manual laborers, clerical workers, the semiprofessional and minor executive group, housewives, the retired or unemployed and, finally, the student group. (All of the students were under 25 years of age.) The differences are not great and, in this series at least, occupation has not seemed to play a highly selective part. The high incidence of coronary artery disease in a group of Jewish industrial workers has recently been pointed out, but the observations were not controlled by postmortem examinations.—

R. L. Levy, H. G. Bruenn, and Dorothy Kurtz, *Am. J. Med. Sci.*, 187, 3: 376-390 (Mar.), 1934.

The Prevention of Occupational Diseases—As a step toward prevention, "differential diagnosis" is of great importance. Most general practitioners count among their patients a very large proportion of industrial workers. The patient's description of his occupation is often most misleading.

A table on mule-spinners' cancer due to mineral oil, 1923-1933, shows the peak of cases to have been reached in 1927 and 1928 when there were 101 cases each year. These have fallen off to a total of only 39 in 1933. The decrease in deaths has been from 36 to 23. A second table shows the reported cases of industrial disease or poison (for England, Scotland, and Wales) for 1900, 1910, 1920, 1930, and 1933. Lead poisoning in particular has fallen off (1,058 to 168 cases, and 58 to 19 deaths).

The first step in prevention is the notification (reporting) by the medical practitioner. This includes also house physicians at hospitals. At this time only 2 definite forms of pneumoconiosis are well established—silicosis and asbestosis. The next step is comprehensive sanitation of the workplace. Another aspect is the medical examination of employees. Toxic agents should be prohibited only when an absolutely competent substitute has been found as, for example, leadless glaze in the potteries. Otherwise, regulations must prevent the absorption of toxic substances into the body. Those exposed to toxic substances should be periodically examined, keeping in mind the specific tests for the given poisons such as punctate red cells in lead exposure. The State Department has devised cautionary placards for display in connection with many harmful substances.

Apart from nystagmus and certain other diseases of miners, dermatitis stands out preëminently. A summarizing table by occupations is given for the years 1928-1932 which shows a gradual increase in these afflictions from 1,367 to 1,940. A central industrial clinic should be established not only for diagnosis but for the better training of medical students, also the facilities for research.—John C. Bridge (H. M. Senior Medical Inspector of Factories). *Lancet*, 5766:471-75 (Mar. 3), 1934.

Sulphur Dioxide for the Fumigation of Ships—Sulphur dioxide has been used for many years in the United States for the disinfection of ships. It was the principal method until 1914 when hydrocyanic acid was introduced. About 30 per cent of ship fumigations are still performed with sulphur. The methods of use, amount, and time of exposure, defects, effectiveness, toxicity, dosage, fumigation of loaded vessels, and hazards are described. There is still not sufficient accurate data at hand to evaluate this method.

It is tentatively suggested that the minimum standards should prescribe that concentrations of not less than 2 per cent SO_2 by volume should be produced in spaces fumigated, and that exposure should be for not less than 6 hours from the time of starting the gas nor less than 4 hours from the time when a 2 per cent concentration is reached.

—C. L. Williams, *Pub. Health Rep.*, 49, 3:89-100 (Jan. 19), 1934.

Methylene Blue in the Treatment of HCN Gas Poisoning—Author's conclusions:

It was apparent from these experiments on rabbits, white rats, and guinea pigs that injections of 1 per cent methylene blue solution were of no value in the treatment of hydrocyanic acid gas poisoning where the animals had absorbed, by breathing, lethal or near-lethal doses of gas in a short period of time. There was a slight variation of results in the different animals used, but the average of results indicated no advantage in favor of methylene blue treated animals.

—J. A. Trautman, *Pub. Health Rep.*, 48:1443-1447 (Dec. 1), 1933.

The Behavior of Lead in the Animal Organism. III—Colloidal Lead Compounds—Tertiary and secondary phosphates of lead, being relatively insoluble, are chemically and physiologically inert in the blood as compared to the soluble salts of lead and colloidal lead when injected intravenously. Thus soluble lead salts are not converted quantitatively into inorganic lead phos-

phates. The conclusion that lead is carried in the blood in the form of inorganic phosphates is therefore untenable.

Colloidal lead is almost as reactive in the body as the water-soluble salts of lead. In the treatment of malignant tumors selective localization of lead in tumor tissues is apparently small. The spleen and liver, as well as the lungs, may be expected to remove the greater proportion of lead from the circulation. Originally high concentration of lead in these tissues will diminish rapidly, except where the relatively inert lead phosphates are used, through the migration of the lead into the skeleton, and through excretion from the body.

Lead compounds are not stored in living tissues in inert form. Lead continues to be excreted from the tissues until there is a balance between that

which is being excreted and that which is being absorbed. The latter is the result of unavoidable contacts with lead materials and elsewhere. Lead deposition and metabolism in the tissues are not different in principle from those of the common mineral elements of the body.

There is a continued diminution in the actual quantities of lead found in the tissues (after intravenous injections) so that after a period of 5 or 6 months there is little evidence of a further drop in the total amount, due to the establishing of an equilibrium with the environment. The presence of such amounts of lead, months after its experimental administration, must not be interpreted as evidence of its retention by the tissues.—Robert A. Kehoe and Frederick Thamann, *J. Labor. & Clin. Med.*, 19, 2:178 (Nov.), 1933.

EDUCATION AND PUBLICITY*

From Chairman of Public Health Education Section—

Recognizing that much of the public health progress of the future will depend upon the development of successful methods of health education, the American Public Health Association some years ago organized the Public Health Education Section. Health education is rapidly becoming a specialty within public health. It is a necessity for both adults and school children. It plays an important rôle in health departments, schools, voluntary health associations, both local and national. There appears to be still some question as to whether the health educator is a soap box orator, a propagandist, advertiser, a scientist, or a

combination of all four. As soap box orators we have attracted only those who had nothing else to do but listen. As propagandists we have been suspected of exaggeration. As advertisers we have doubtless annoyed some to whom our message did not appeal. As scientists we have still to develop technics of proven effectiveness.

It is the purpose of the Public Health Education Section to serve as an open forum for the discussion of these and other problems so vital to our profession. The usual annual Health Education Institute will be held preceding the 63d Annual Meeting of the American Public Health Association in Pasadena, September 3 to 6, 1934. The theme of this year's institute will be School Health Education, although the discussions will be of equal value to those who are engaged in adult education.

* Health Education Section, supplies of printed material, or forms of material which appears herein, etc., to East C. Printing Co., 115 East 124th St., New York, N. Y.

The program of the section, besides featuring a joint session with the Health Officers Section, will present discussions by experts, both from the East and the West, in our special field. At the closing session a specially appointed representative will summarize the highlights of what has gone on in other sessions of the section. It is a meeting which none interested in public health education can afford to miss.—W. P. Shepard, *Chairman*, Public Health Education Section, American Public Health Association.

"American Health Propaganda"
—As some of it looks to an Englishman, is discussed by Elwin H. T. Nash, Medical Officer of Health for Heston and Isleworth.

I have been asked to deal with publicity, mainly, I gather, from the point of view of publicity with a punch, owing to the fact that I have been investigating the various methods, particularly American, of pushing public health matters. Afterward it may be a matter for consideration whether its methods are best, or inadvisable for maternity and child welfare work. There is no doubt that in connection with matters like diphtheria immunization they do achieve the object in view.

Speaking generally, our methods of propaganda in public health matters are so respectable indeed that they get us nowhere. For example, we circulate little sober-minded articles in the paper *Better Health*, which is utilized by a few public authorities, and then, as a rule, that circulates only to the converted. Possibly we put up little posters in shop windows, which have got no particular bite and get mixed up with a similar sized advertisement of a "Social Tea at the Local Church Hall."

Of course, Dr. Nash is laying it on a bit thick for emphasis. Both in quantity and quality a fine job of public health education is being done in England. Dr. Nash continues:

We in this country are not so ostentatious in our methods as they are on the other side of the Atlantic, and that may possibly be due to the fact that the populations on the other side are more mixed and contain more of the temperament of middle and southern

Europe, which is more used to flamboyant and jubilant methods of expressing its emotions.

As an example of the way in which things are done in America, where every organization is roped in to assist, I am going to give you an account of a campaign in New York.

. . . In New York, the funds for a certain campaign for diphtheria immunization were found by the Milbank Memorial Fund and the Metropolitan Life Insurance Company.

Then follows a long summary of that campaign, with references to Honolulu and New Haven.

In addition to posters the Americans go in very largely for small pictorial pamphlets dealing with all sorts of activities in the public health work. They also use the schools enormously by circulating puzzles and such like things worded with the slogan they are trying to put across. All this is done on the basic understanding that constant reiteration of any phrase eventually gets into the intelligence somewhere.

Dr. Nash mentioned our use of radio and motion pictures, and spoke enthusiastically of a 16 mm. picture taken in his own clinic, closing with a reminder that

Pictorial publicity, one has got to realize, is expensive if continuous, and it is a matter for very mature consideration whether that amount of money spent on the salary of an efficient health visitor is not going to produce results which are better in the long run. It is only the tactful and efficient health visitor who can, after several refusals, get inside the house and break down the barrier of resistance that is greatest, as a rule, in the houses where the need is most, and I am afraid it is these families which are going to be least influenced by sober-minded pictorial advertisements.

In any advertising display there must be a punch of some kind, but it must be strictly truthful.—

Ways and Means of Propaganda.
Mother and Child, 5, Tavistock Square,
London, W. C. 1. Aug., 1933. 9d.

An Official Declaration—The Subcommittee of the Committee on Administrative Practice proposed and the American Public Health Association

formally approved at Indianapolis of the following statement of "desirable standard minimum functions" in public health education:

Modern public health practice has shown how to prevent a large proportion of sickness and premature deaths. It is a responsibility of health departments to make this knowledge accessible to the average man, in a form which he can understand and make a part of his living. This may be accomplished through such channels as general newspaper or magazine publicity, the distribution and publication of books and pamphlets dealing with subjects of personal or community health, through lectures, personal and group demonstrations, using lay and professional staffs, through pictures and exhibitions.

State health department functions were declared to include:

Collection, tabulation and publication of vital statistics for each important political or health administration unit of the state and for the state as a whole.

Collection and distribution of information concerning preventable diseases throughout the state.

In American Public Health Association *Year Book*, 1933-1934, pp. 8 and 9.

What Should Be Taught in Junior High Schools—From widely separated states comes news of new efforts to place high school presentation of health upon the highest plane.

We hope that readers will contribute to the study being made by Dr. William P. Brown, Medical Inspection Bureau, State Education Department, Albany, N. Y., whose problem is here stated:

The Division of Health and Physical Education of the State Education Department is reviewing the health program for junior high schools and is expecting to revise the content and methods. It is planned to include in grades 7 to 9 a fundamental understanding of the causes of common diseases and an appreciation of the dangers of self-medication and of delay in treatment. The policy of the Education Department has for some time excluded systematic attention to diseases in the health syllabi for the elementary grades, 1 to 6.

This study will be developed during the

next 12 months and is aimed to increase the far-reaching influence of the high schools in the public practice and understanding of health. Readers of the *American Journal of Public Health* who have in mind items of improvement in this field, or errors to be avoided are invited to send suggestions to Dr. Brown.

What methods and to what scope should the mental hygiene be incorporated, and under what auspices could instruction in family relationships and discipline be included?

Scientific outlines of the preventive principles concerning such prevalent diseases as rickets, typhoid fever, smallpox, diphtheria, tuberculosis, cancer, goiter, syphilis, rheumatism, etc., might be phrased to be of value to the child in the events of post-school life, and could also be of value in parenthood that will follow normally in the next decade for these future citizens.

Suggestions as to textbooks are also desired.

Yellow Fever in New York City—"Yellow Jack" on Broadway suggested to Attention-Caller Zimand that he send us a page from a March, 1930, issue of *Weekly Bulletin*, New York City Health Department.

The *Bulletin* editor, in looking through some old records had noted that

Almost every year from 1795 to 1805 deaths from this disease appear in the records, causing many to flee the city and giving rise to great fear and alarm among the people.

The worst of these epidemics, during 4 months commencing the end of July, 1798, caused nearly 1,500 deaths. At that time the population of the city was approximately 60,000 and the total number of deaths from all causes averages slightly more than 2,000 per annum.

Of 40 physicians listed in the 1785 City Directory, 16 died of yellow fever.

Old records and old newspaper files may yield usable examples to point the moral of progress in public health in almost any community.

Why They Are Not Listed—We aim to list all materials coming from

national sources in the United States and Canada, and materials available generally to health workers in either or both countries.

Sometimes publications or other materials are held up so that we may write for desirable information that has not been given. Frequently we never get the letters written. So please send the information with your materials. When we take a chance we frequently get the "facts" wrong.

We fail to list much of the materials from national sources *especially from national health agencies, both governmental and others, because only a few of them send copies of their new issues and their lists of materials.* That accounts for some nationals never being mentioned, although other nationals frequently get into this department.

Motives in Health Education—*"You and Your Community"* is treated in the Sept., 1933, issue of *Health Bulletin for Teachers*, Metropolitan Life Insurance Co., New York, N. Y. The introductory paragraphs discuss motives:

Until recently, fear was the motive commonly used in the formal type of hygiene teaching in schools. "Be vaccinated to avoid the danger of smallpox." "Don't spit—it spreads disease." The avoidance of undesirable results is a valid but limited motive and its use has serious drawbacks.

A second motive, and the one which is now dominant in many school programs of health teaching, is the positive appeal to the desire for individual achievement. "Exercise so that you may win athletic competitions." "Drink milk so that you may grow up to be a strong and successful man." This is a valid motive at a certain stage of child development and is a great improvement over the fear motive.

The third motive is the recognition of social responsibility. Membership in a group involves privileges and responsibilities. Together we can attain advantages which we could not gain as individuals. A study of the community health program well illustrates this fact and develops an admirable correlation between hygiene and civics.

Health Education Duties of Physicians—In "Duties of the Profession in Health Education" Dr. W. W. Bauer reviews some misconceptions of doctors and laymen, discusses some "expensive forms of public health work which ought to have been done

by the family," and reviews some "high lights in the field of medical participation in public health work."

Granting that the public is entitled to information about its own health, it seems self-evident that the medical profession is obligated in the public interest to supply such knowledge. So also are health departments and public health leagues, tuberculosis associations and similar voluntary health organizations. In fact, the proper functions of such organizations, as the best of them recognize, should be educational exclusively. In the field of health education, so-called, will also be found commercial organizations of various kinds supplying health information, some of it of the very highest type and some of the very lowest and most reprehensible. How is the layman to discriminate if his doctor does not help him? He is assailed on all sides with health education or what passes for health education. The utmost cunning is exercised by commercial exploiters of the health motif. Public health departments have not always been as scrupulous as might be desired in avoiding tie-ups with commercial exploiters, buying a temporary advantage in publicity at a price which included sacrifice of their own standing as disinterested purveyors of facts.

The doctor's duty is clear. How shall he proceed to discharge it? The first question that is usually raised is that of ethics. It is easy enough to answer. Health education is not advertising in itself. It can be misused so that it constitutes advertising, or it can be kept, as it ought to be kept, education purely. The choice is sufficiently plain. In every corner of this country, the medical profession is taking up, to a greater or lesser extent, the problem of health education.

Posters Prevent Traffic Accidents —So says National Safety Council.

Pittsburgh and Evanston, joint winners of the National Traffic Safety Contest last year, made extensive use of posters and outdoor displays. Nearly every city in the contest which received a high ranking under the "Public Education" item carried a direct safety appeal to the public in the form of posters.

As a compilation of the experience in many cities, the National Safety Council has issued a memo—Public Safety Memo No. 81—on "Using Traffic Posters."

The most common size for traffic posters is 25 x 38 inches. This is large enough for outdoor posting and not too large for use indoors.

A smaller size, 17 x 23 inches, is often used where it may be approached closely enough to be read easily. Occasionally, large multiple-sheet posters for highways billboards are used, but there is no national organization that regularly publishes traffic posters for these big boards.

The memorandum tells where to display the posters, how to get them posted, and how to make the display boards.

The National Safety Council publishes traffic posters regularly. Each month one new two-color poster with the same slogan and design in each of two sizes is issued. In addition, there are published from time to time smaller posters which are suitable for traffic use. Forthcoming posters are illustrated in *Public Safety* the month previous to publication, and in *National Safety News* for the month of issue. Posters are also available from some automobile clubs and insurance companies.—

Address National Safety Council, 20 N. Wacker Drive, Chicago, Ill.

Adults Can Learn—No longer may failures in adult health education be laid to the learning inability of the adult. The basic studies by Edward Lee Thorndike leave no doubts as to possibility of teaching grown-ups.

Dr. Thorndike reports briefly on investigations which are detailed in full in *Fundamentals of Learning*, a Teachers College publication. We quote:

All of the 104 experiments reported in this volume were with adults, with an age range of from 20 to over 50. In these fundamentals of learning we have so far found no differences between the twenties and the forties. As was shown in the report published as the volume "Adult Learning," there is a slow decline in the ability to learn from about 25 on, but there are no observable differences in the nature of the fundamental and general forces which make learning possible. The "Adult Learning" encouraged workers in this field by demonstrating through extensive experiments that their task was possible and hopeful and that their opinions to that effect based on their own experiences in teaching adults were not illusory or prejudiced.

The *Fundamentals of Learning* may encourage them further to expect that no peculiar

pedagogy is necessary in teaching adults. The task of teaching at all age-levels is to put together in the mind what should go together, and to make these connections satisfying. The facts, skills, abilities, etc., which are suitable to be taught to adults often differ from those suitable for children, but the general procedure by which any information, skill or power is developed does not. What will interest and satisfy adults differs, of course, in important ways from what will interest and satisfy children or adolescents, but the general process by which a satisfying after-effect confirms the behavior that produces it does not. The general laws of human modifiability do not change with age. Procedures that are fundamentally sound (or unsound) in learning and teaching at age 10 or 20 will be so at age 30 or 40 or 50.—

Journal of Adult Education, 60 East 42d St., New York, N. Y. Jan., 1934. 75 cents. This is a paper-bound volume of 125 pages. An issue every 3 months. A publication of fascinating interest to those concerned with the thinking and practising in the many fields of adult learning in this country.

In South Africa—"Health publicity and educative work" is a sub-title of the annual report of Dept. of Public Health, Union of South Africa, Pretoria. In addition to the familiar topics for pamphlet or leaflet presentation we find publications on daggo smoking and snake-bite.

The department offers 13 motion pictures, including one on bilharziasis; a set of models loaned for "health weeks" and other events; and lantern slides, with 3 magic-lanterns—all offered to "ensure the coöperation of an enlightened public."

Lead, Not Follow, in Use of New Ideas—Business and industry have advantages over health and social work in larger budgets for writers, artists and printed matter—but they have no monopoly of ideas. Years before business discovered cut-out photographs, silhouettes and sketches, and three-

dimension letters, we were urging their use in exhibits and displays.

Inanimate objects are beginning to talk in advertisements: fine instruments, tooth brushes, light bulbs. How about test tubes, birth records, disease germs, clinic doors . . . ?

"Streamlining" and "wind resistance" are being applied to "strip your . . . of non-essentials . . ."

But as one advertiser says: "a great deal depends upon the skill, ingenuity and imagination with which it is interpreted."

Anyway let's use 'em before they become threadbare.

"Ill-Advised Propaganda"—Under this heading are reports of two addresses at a meeting in London to consider the Final Report of the Departmental Committee on Maternal Mortality and Morbidity.

Dr. Agnes Young, assistant county medical officer, Warwickshire, is

. . . impressed with the detrimental effect of fear of pregnancy upon the expectant mother. She lays considerable blame at the feet of the lay Press for this situation, as she considers that undue prominence is given in the newspapers and other lay periodicals to the question of maternal mortality, and given in such a way as to induce fear rather than confidence. This fear, she considers, must be counteracted. If this dread is dispelled during pregnancy, she says, there is much less chance of an otherwise normal delivery being adversely affected by any psychological factors, for undoubtedly fear can inhibit proper uterine contraction, resulting then in instrumental delivery, and at added risk of infection.—

Mother and Child, London. Apr., 1933.

BOOKS AND REPORTS

Pediatric Nursing—By Gladys Sellew, M.A., B.S., R.N. (3rd ed.) Philadelphia: Saunders, 1934. 609 pp. Price, \$2.50.

This well written textbook presents in a clear and interesting form a broad and comprehensive study of pediatric nursing together with as detailed a survey of the physical and mental development of normal children as can logically be included. The book is the result of years of experience in working with children and in teaching pediatric nursing.

In plan it follows closely that of the second edition, but much new material has been added following recent developments in pediatric practice. The questions appended to each chapter are specific and particularly helpful to the student not yet adept at grasping and organizing the important facts in newly presented subject matter. The illustrations included are relevant and instructive but too few in number. It is the reviewer's belief that a good illustration accompanying the description of a procedure is one of the most effective of teaching aids. As an example, note the illustration of three methods of carrying a child given on page 119. The description of the procedure is clearly written, but the illustration can be more quickly and thoroughly comprehended by the average student and will be remembered longer.

Except that the book is already long for the amount of time generally devoted to class work in pediatric nursing, the chapter on occupational and recreational therapy could well be enlarged. The list of reference books upon child guidance and play materials is stimulating and the books suggested for the enjoyment of children them-

selves will prove helpful to those who have little familiarity with the literature of this field. The binding, printing and indexing meet all requirements for textbook use.

The third edition of Miss Sellew's *Pediatric Nursing* is welcome not only as a textbook for the permanent possession of each nursing student, but can be studied with profit and pleasure by any graduate nurse interested in keeping well informed about all lines of medical and nursing progress and by the married nurse who uses her training only for the welfare of her own family and her influence among a small circle of friends.

HAZELLE BAIRD DOUGLAS

Physiological Effects of Radiant Energy—By Henry Laurens, Ph.D. New York: Chemical Catalog Co., 1933. 610 pp. Price, \$6.00.

This book is an American Chemical Society Monograph. It is primarily a source book on the nature, physics, and effects of radiant energy as applied to human physiology. The subject matter is well arranged and the style is clear.

The chapter on the physics of radiant energy is most complete and up-to-date.

By far the largest part of the text is concerned with the effects of ultraviolet radiation upon metabolism, the balance of the book being devoted to the effects upon the skin, the eye, the circulation and the blood, and a chapter on photo-dynamic sensitization, which reviews the various theories held by different observers of this phenomenon.

The final chapter on the mode of action of radiant energy brings out the consensus of prevailing thought on this question and summarizes it very well.

The bibliography is exhaustive, ex-

cupying 15 pages, and has its alphabetical index. A complete list of authors and subjects is also included.

The book as a whole is an excellent review of the work done to date in this particular field. All who approach the subject from a scientific point of view will find it a splendid text, but for the general medical man it is much too technical and theoretical.

It is well set up, quite readable, sturdily bound, withal a very good book.

H. M. HERRING

Blindness and the Blind in the United States—By Harry Best. *New York: Macmillan, 1934.* 714 pp. Price, \$6.50.

This volume is a revision and an expansion of *The Blind: Their Condition and the Work Being Done for Them in the United States*, Macmillan, 1919. With what must have been a prodigious amount of labor, Dr. Best has brought together a wealth of well-documented material and has given us a book which will rank as the standard reference work in its field.

The author emphasizes the fact that the attitude of society toward the blind is too frequently one of compassion only; that concern in the blind based upon their actual position in society and the treatment accorded them is seldom shown. His treatment of the subject is that of the social economist. The blind are regarded as certain components of the population who demand classification and attention in its organization. The problems created by the presence of such a group and the measures taken to adjust the group to society are here carefully set forth. The result is a study, detailed and comprehensive.

The material is arranged in seven parts as follows: Blindness and possibilities of its prevention, General condition of the blind, Provision for the education of blind children, Intellectual

provision for the adult blind, Material provision for the blind, Organizations interested in the blind, Conclusions with respect to work for the blind.

LUCILLE A. GOLDTHWAITE

Health Education in an American City—By Louise Franklin Bache. *Published for The Milbank Memorial Fund. New York: Doubleday, Doran, 1934.* 116 pp. \$2.00.

When Syracuse began its health demonstration in 1923 health education was recognized as a legitimate member of the family and took its place on equal terms with sanitation, engineering and epidemiology. This was an acknowledgment that while we, the sovereign people, will be led, duped, and cajoled, we will not have thrust upon us something that is new unless it is popularly interpreted.

Miss Bache, who directed the health education program, gives us a faithful account of the methods used and the results that followed. Theories and precepts about health education we have had in abundance; reports of excellent but isolated enterprises have inspired us; but this is the first full record of actual work done on so comprehensive a scale. It is the equivalent of an extensive laboratory experiment meticulously reported, and as such serves as a guide to all of us. We glean from it many helpful hints about the use of the newspaper, the radio, the spoken word, and other media of thought-exchange; but what is still more valuable, we learn the importance of carefully planning a publicity project as a whole. Apparently the various publicity media were not indiscriminately "fed" on whatever pabulum happened to be lying around loose but each was selected to serve the particular need of the plan at a particular time.

One lesson the reader will learn is that health education is not an entity

independently pursuing its own purposes but rather the vocal organ of the entire health department. Another is that the art of publicity is neither black magic nor a capricious gift of the gods, but honest toil plus a pinch of inspiration.

H. E. KLEINSCHMIDT

Public Sewerage Systems in Germany—By *Prof. Dr.-Ing. E.h. J. Brix, Dr.-Ing. E.h. Karl Imhof, Prof. Dr. R. Weldert. Jena, Germany: Gustav Fisher, 1934. 2 vol. 298 fig. 1549 pp.*

The work here reviewed represents the completion of a stupendous undertaking. The general principles underlying the design of public sewerage systems and of sewage treatment are given generous space, while figures for water consumption for domestic and industrial uses, the laboratory examination of sewage and sludge, and the discussion of administrative units for the control of sewerage systems and sewage treatment, such as sanitary districts, are presented at length.

Complete descriptions of the sewerage facilities in all of the German cities are given with a degree of detail varying with the size and complexity of the system, but in every instance the sewage treatment plant, pumping stations, the basis for design and the costs, are included.

It is difficult, in a brief review, to do complete justice to the enormous amount of work involved in the preparation of these two volumes. The text supplies a new reference volume which we might well emulate for similar systems in this country.

The books are excellently printed, the paper is of fine quality, the drawings and photographs are carefully reproduced and an obvious and successful effort has been made to provide the reader with easy reference to all of the information.

ABEL WOLMAN

Adolescence—By *Beverly R. Tucker, M.D. Boston: Stratford Co., 1933. 121 pp. Price, \$1.25.*

A book on adolescence is always received with interest, since the subject is important and the literature meager. This particular one is somewhat disappointing. The author has the necessary qualifications to deal adequately with his theme, but too much of the book is given over to brief references to most of the diseases which human beings in the adolescent stage might have (and his limits for adolescence are 9 to 25 years of age). Parents, teachers, boy and girl scout leaders—for whom the book is written—will get an exaggerated impression of the dire things which are likely to befall their children or charges; especially as mouth-filling psychiatric terms are used in all their glory with equivalents in parentheses. Many of the statements are very dogmatic and sweeping, as for instance, "Indoor exercise is rarely beneficial and indoor swimming pools and gymnasiums with their poor ventilation and easy exposure to infection are dangerous." The short chapter on "The Sex Question" is quite inadequate.

It is a pity that the author did not write either a larger book for trained workers or a different type of book with the technical matter largely omitted, its place being taken by an amplification of the hygienic rather than the disease aspects of adolescence.

MERRILL E. CHAMPION

The Foundations of Nutrition—By *Mary Swartz Rose. (rev. ed.) New York: Macmillan, 1933. 674 pp. Price, \$3.00.*

"This book is written for those who wish to live more intelligently." The manner of treatment is based on the writer's experience in teaching nutrition to beginners. There is an interesting historical introduction, followed by the

physiological facts showing the need of the body for energy and the amounts required for adults and for children, as well as the recognized methods of measurements. Various factors causing variation in the basal metabolism of individuals are well discussed. Then follow chapters devoted to calories, to the vitamins, and to the substances from which we obtain our foods. Sound advice on the construction of adequate diets is given not only for adults, but also for preschool, kindergarten, elementary, and high school children. An especially valuable chapter is that on the food needs of mothers and babies. There are 9 valuable appendices giving tables which every student of nutrition needs to consult more or less frequently.

There is an interesting section on the relation of food to diet, a distinction which is so little understood by many people who should know better. The author describes the method of estimating foods according to "shares" and gives figures representing graphically the different values of an orange and a potato, for example, while in Table 1, the value of the foods is given in "shares" of the principal elements as well as the vitamins. The share is based on the average diet for an adult of 3,000 calories, which the author conceives of as being made up of 30 portions, the values of which are given. A share, then, is one-thirtieth of the day's requirements and is given for energy, protein, calcium, phosphorus, iron, and vitamins A, B, and C.

We have called attention to the chapter on food needs for mothers and babies. This begins with a quotation from Arnold Bennett: "The baby owes nothing at all to his parents. . . . The parents owe everything to the baby . . . we are bound to see that children are given the best opportunity to develop to the limit of their growth capacity."

The historical introduction recites an

observation of great significance, dating back to 607 B.C., which emphasizes the old adage that there is nothing new under the sun. Nebuchadnezzar, after capturing Jerusalem, selected a number of youths for training as courtiers, who were to have a special education and a daily portion of the king's meat and wine. One of them objected to this diet, and proposed that they be given a 10-day test during which they were to eat pulse and drink water. At the end of the 10 days they were fairer and fatter than the children who ate the king's meat, so that the steward continued this diet, and at the end of their probation, the king examined them and found that they scored 10 times better mentally than all the magicians and enchanters in his realm.

The book is most interestingly written. The printing and illustrations are excellent. It seems a work of supererogation to recommend a book which is so well known through the first edition and written by the author whose name gives assurance of study and accuracy. MAZÛCK P. RAVENEL

Mystery, Magic, and Medicine—By Howard W. Haggard, M.D. New York: Doubleday, Doran, Inc., 1933. Price \$1.00.

The author of *Devils, Drugs, and Doctors*, and other books, has dedicated this account of "the rise of medicine from superstition to science" to Dr. E. R. Squibb whom he characterizes as "a pioneer in the advancement of scientific medicine."

It is a condensed story of the development of modern medicine with its beginnings in mystery and magic and its steady progress to the present-day status.

The far reaching influences of the fundamental sciences are recognized. The reader is given glimpses of personalities who played an important part in this triumphant march. Photographs of

these men, and documents are additions to the book.

A glossary of proper names and medical terms makes up the last fourth of the book.

The style is interesting—the author presents facts in a very readable, attractive way, and any person will find the book worth while as a brief account of the evolution of medicine.

ANNA DEAN DULANEY

Food, Nutrition and Health—By *E. V. McCollum, Ph.D., Sc.D., and J. Ernestine Becker, M.A., Published by the Authors, East End Post Station, Baltimore, Md., 1933, 146 pp. Price, \$1.50.*

Due to the great demand for this small book which presents the established facts about the relation of nutrition to health in simple, non-technical language, the authors have presented a new and rewritten (third) edition.

In the introductory chapter, the nutritive needs of the body are set forth briefly. Here one can obtain in simple language the answer to "What Constitutes An Adequate Diet?" Chapter III discusses Carbohydrates, an added feature to the previous editions. One who does not possess knowledge of nutrition and who questions the information so widely disseminated by faddists and promoters of special foods will find this book highly instructive. The three chapters on "The Diet and Preventive Dentistry," "The Reducing Diet," and "How to Increase the Weight," are especially recommended.

In keeping with the times, the wisest spending of the money allotted for food in the family budget has been stressed. The last chapter on "A System of Diet Which Promotes Health" gives a few simple principles and a list of menus for the different seasons of the year.

The print is rather fine and there are no illustrations. Home economics teachers, dieticians, health educators,

nurses, social workers, extension workers and others will find this book a valuable and in their teachings of how to live so as to further health.

BESS EXTON

The Century Childhood Library—

Edited by John E. Anderson, Ph.D.

New York: Appleton-Century, 1933.

3 Vols. Price, \$2.50 each.

This library is well named; the three volumes form an excellent library dealing in sufficient detail with the physical and mental aspects of childhood. Parents with this "Five Inch Shelf" to consult and with the intelligence to make proper use of it ought not to go far astray. All three books are for the educated parent; they are a little over the heads of the many who rightly look for guidance to the innumerable pamphlets and leaflets put out by official and unofficial agencies. A brief indication follows of the many good things to be found in these books.

Busy Children, by Josephine C. Foster, Ph.D., is best described by its subtitle "Guidance through Play and Activity." The meaning of play; the selection of toys; play with and without apparatus; games and sports; making things; are discussed in some of the chapters. An important section deals with the child's participation in the family activities and another with education at home and at school. There are others equally interesting and thoughtfully worked out. A summary at the end of each chapter serves a useful purpose.

Happy Childhood, the contribution of the general editor of the series, John E. Anderson, Ph.D., deals with what is usually called child guidance or mental hygiene. It has been said that some books can be read by looking over their table of contents. That is not true of this one; nevertheless, that table does give the reader a pretty good idea of what he will find in the 20 chapters, all

of them good and thought-provoking. The background of the child; his equipment for living; his various "quests" as the author puts it—for security, affection, knowledge, social esteem and so forth and the problems involved. Other chapters have to do with the gifted child and with the handicapped child. There is a valuable chapter on parents and homes; another on self control and discipline. Free use is made of the White House Conference data—the author was chairman of one of the committees of that Conference.

Healthy Childhood, by Harold C. Stuart, M.D., the third volume in the series, is in many ways the most complete book available on the subject of the physical aspects of child hygiene, intended for the use of the layman. The usual phases and some that are less usual, are discussed in ample detail; such as the anatomy and physiology of the child's body with practical applications to child hygiene; the principles of nutrition and their relationship to the feeding problem; rest and activity; infection, immunity, and the prevention and treatment of infectious disease; control of environment; accidents. The last chapter deals with special features of care at different ages. An appendix takes up the more common diseases of childhood. Additional features have to do with the child health movement; preparation for parenthood; and characteristics of growth.

A few points will occur to the public health trained worker about which there might well be a difference of opinion. In the chapter on the child health movement, no mention is made of Josephine Baker's pathfinding work in New York City in 1908 and after. Her bureau of child hygiene, nominally a city affair, was really the source of most that followed in the national field. The impression is given, it seems to me, that the reduction in infant mortality is pretty much due to the efforts of

health workers. I wish that this could be proved: it would be very comforting to some of us who have labored long in the vineyard, but how much of the evidence is based on wishful thinking?

Other minor points come to mind. For example, the use of fuming nitric acid in the treatment of dogbite is usually considered safer practice—based on experimental evidence—than the use of silver nitrate or other cautery referred to in the text. The author goes into too great detail in spots on the subject of quarantine. This is a matter entirely within the province of the health department and the periods given in the book may not agree with those of the department within whose jurisdiction the reader may be. It would be better to give more explanation of official relationship to communicable disease. Finally, the index could be expanded somewhat to advantage. A good point about all three books is that each has an index of its own and a combined index to all three.

Healthy Childhood can be recommended without reservation as a *vade-mecum* for the intelligent and conscientious parent, and to all others as well who are interested in obtaining a sound outline of child hygiene.

MERRILL E. CHAMPION

Windows on Henry Street—By Lillian D. Wald. Boston: Little, Brown, 1934. 348 pp. Price, \$3.00.

This book takes up the thread of Miss Wald's story where her previous book, *The House on Henry Street*, left it in 1915.

The present volume really acquaints one with Lillian D. Wald, yet cannot be classified in the least as an autobiography.

The author has looked out of the "Windows upon Henry Street," and witnessed the changes year by year, has seen the intimate home life of the people of a congested neighborhood,

people with limited chances, pinched lives, and smothered emotions—and she has dared to dream above such stifling, suffocating conditions into a future for a quickened and an awakened social consciousness whereby changes have been made, and in the future to a greater extent will be made, affecting the conditions of and greatly uplifting human life—thus making true a Human Progress in which the new generations will surpass the previous.

In this book one sees the long line of humanity passing into and being changed by the light that shines through those "Windows on Henry Street"—the sick, the widowed, the aged, the young, mothers, fathers, children, the mental defective, the wage earner, the poorly housed, the poorly clothed, the bigoted, the spiritually crushed—and then sees them emerge filled with hope,

faith, and courage, to press hopefully back against their problems and as they go on into life to spread the message of cheer so that it passes around the world touching untold lives bordering upon its pathway.

Those selfsame "Windows on Henry Street" have also let one glimpse into the very heart and soul of the woman who has played the chief rôle behind them—the real Lillian D. Wald stands revealed.

The message of the book is—"we have found that the problems of one set of people are essentially the problems of all. We have found that the things which make men alike are finer and stronger than the things which make them different—that people rise and fall together, that no one group or nation dare be an economic or social law unto itself." CHARLES HAMMOND

REPORTS

Julius Rosenwald Fund—In the 2-year review for 1931–1933, the President of the Fund pays fitting tribute to the founder and outlines the varied interests in which the Fund participates. Planning of Indian education, coöperation in Negro welfare work, studies of education in American Samoa and in the Dutch East Indies, are among the activities discussed. Objectives of education in various cultures are analyzed. The Fund's attention is given to these problems because of concern for racial adjustments in this country and the world over and because of its interest in the general subject of education.

The Division of Medical Services is carrying on a program which includes a general information service on the economic aspects of medical care and service, studies and appraisals of plans

and experiments in group practice and group payment, and consultant service and professional aid.

New Jersey—The year ending June 30, 1933, was marked in New Jersey by the application of a new milk control law, by enlargement of the laboratories and other quarters of the State Department of Health, and by enactment of other public health laws for future enforcement. The new milk act made necessary, following inspection by a New Jersey public health official, the approval if indicated of every dairy and milk plant from which milk and cream to be used in fluid state is shipped into New Jersey. Included in this group were some 35,700 dairy farms and 319 milk plants located in the states of New York, Pennsylvania, Delaware, and Maryland. The use of

temporary permits became necessary in view of the magnitude of this task.

Approval was given by the Department for reclassification of water purification and sewage disposal plants for purposes of licensing operators and the adoption of definite qualifications, based on training and experience to be met by applicants for licenses. Also, minimum standards of sanitation were adopted for roadside stands, restaurants, soda fountains, lunch rooms, and similar places.

Hamilton, Ontario—A comprehensive health survey report of 72 pages describes the health organizations and relationships in Hamilton, Ontario, and offers carefully framed recommendations for continued progress. The record shows marked achievement in health activities in this city of 155,547 population, indicating a rating of over 85 per cent on the *City Health Appraisal Form*. The report, however, emphasizes the importance of trained personnel and of closely coördinated activities.

Among major recommendations are the following of special interest to health administrators:

3. That the Health Division of the Hamilton Council of Social Agencies be asked to act as a Health Council for Hamilton.

4. That the health services of the Board of Education and the Babies' Dispensary Guild be transferred to the Department of Health, and the staffs absorbed into the Department.

6. That the Department of Health recognize the family physician as the most desirable agent for health supervision.

7. That, for purposes of health administration, the city be divided into four or five sanitary areas, with a health centre in each area.

The surveyors point out the existence of a need for a clear-cut decision as to which department of municipal government or voluntary agency is to be responsible for certain matters. They indicate their belief that all relief by

public departments should be provided through the Welfare Commission of the city. Under this heading should be included: extra nutrition, including milk, and eye-glasses. They also recommend that all nursing service in the home be provided by the Department of Health or the Visiting Nurse Association.

Milbank Memorial Fund—The belief is expressed in the 28th year review that public health, as a social function, is concerned not only with direct measures for the prevention of disease and the education of the public in hygiene, but also with the medical care of the sick, the proper administration of relief, and with the prevention of all conditions that are harmful to health, whether they be economic, social, or more directly etiological. If the vitality of the population is to be preserved, according to the Fund's observations, public health and medicine of the future will be concerned with the health of adults as well as that of infants and children, with controlled fertility, and with further modification of harmful conditions of environment. Integration of services in more comprehensive, better planned programs that are more than local in scope is an expressed need.

Referring to the health demonstrations, it is noted that many services developed within the Bellevue-Yorkville area on an experimental basis have been extended to other parts of the metropolitan district. Further, the policy of district health administration through health centers has been adopted and a program of district or decentralized health administration has been undertaken. Studies of how existing public health procedures can be made more effective through increased efficiency of personnel and by more careful selection of individuals who are in greatest need of services are reviewed. The varied

interests of the Fund are suggested by a description of health projects carried on in Ting Hsien, China, under the auspices of the Chinese National Association of the Mass Education Movement. Reference is also made to a recent study of public health conditions in Russia under Fund auspices, and to the publication of the results in the 5th volume of the series of international studies on medical and public health procedures.

U. S. Public Health Service—In a compact volume of 128 pages, the Surgeon General's report of the Public Health Service for the 62nd year reviews world health conditions and describes how the duties of this important branch of federal government have been carried out. Generally good health conditions in most of the countries are noted for the year 1932. Extracts from the report follow:

In 1932, about 75,000 cases of cholera were reported throughout the world, with 39,000 deaths. In 1931, 260,000 cases and 141,000 deaths were reported. Most of the recorded cases occurred in India. In the Philippine Islands 420 cases of cholera were reported during the calendar year 1932, as compared with 936 cases in 1931.

In the United States and in England smallpox was less prevalent in 1932 than it was in 1931, but in British India this disease caused 26,900 deaths in 1932 and 19,000 deaths in 1931.

Plague was widespread throughout the world in 1932. Wherever commerce goes rats are carried, and some of these rats carry plague-infected fleas. Typhus fever, another disease of widespread occurrence, is reported from all of the great divisions of the world. In Mexico typhus fever caused more than 1,000 deaths in 1932 and nearly 1,500 deaths in 1931. In the United States most of the cases of typhus fever are of the mild form, but in many countries where the disease is spread by body lice it is comparatively severe. Yellow fever was reported in several provinces of Brazil during the calendar year 1932 and in several countries in Africa, including French West Africa, Portuguese Guinea, the Gold Coast, and Nigeria. The

numbers of cases reported were not large, but the infection exists in large areas.

During the calendar year 1932 and the first half of the year 1933 health conditions were good in the United States as compared with those of preceding years. The general death rate for the year 1932 was the lowest ever recorded. Infant mortality and the death rates for tuberculosis, diphtheria, and typhoid fever also reached new low records. There were no unusual widespread epidemics, and the principal increases in the death rates over rates for preceding years were for cancer, heart disease, and other so-called "degenerative diseases," the death rates of which have been increasing for years.

During the fiscal year no instance occurred of the importation into the United States or its dependencies of any quarantinable disease. One vessel arrived at the New Orleans quarantine station infected with typhus fever; 1 case of smallpox developed among passengers undergoing quarantine detention at the San Francisco quarantine station; 1 vessel arrived at Honolulu after having had 1 death from cholera on board; and 1 vessel with 2 cases of cholera arrived at the port of Manila. In each instance effective measures were taken at the respective stations to prevent the introduction of these diseases into United States territory.

At domestic ports, 398,574 alien passengers and 805,028 alien seamen were examined by medical officers of the Public Health Service under the immigration laws. Of this number 13,942 passengers and 991 seamen were certified for various diseases and disabilities. The most important causes of certification of alien passengers were as follows: trachoma, 252; tuberculosis, 139; feeble-mindedness, 91; insanity, 72; syphilis, 220; and gonorrhea, 345. Of the alien seamen examined 4 were certified for trachoma; 13 for tuberculosis; 67 for syphilis; 83 for chancroid; and 162 for gonorrhea.

In coöperation with State health agencies, 95 per cent of the 2,214 sources of drinking water used by railroads and bus lines, 97 per cent of the 253 sources used by vessels, and 97 per cent of the 116 sources used by airplane carriers were inspected and controlled by the Public Health Service. Municipal health agencies coöperated in this work by collecting and examining approximately 5,000 samples of drinking water taken from common carriers.

In an effort to determine the effect of the depression upon health, information was collected on sickness and mortality in a group of unemployed families. A 4-year family in-

come history and a 3-month illness record were obtained by canvass of about 1,000 families in each of 10 communities located in 8 large cities and 2 more or less rural places. Preliminary analysis indicates higher sickness rates among the poor, particularly in the case of the more serious illnesses that caused inability to work or that confined the patient to bed. It also appears that those families who were moderately comfortable in 1929 but who had been in poor circumstances for 2 to 3 years had more sickness than those who had only recently become unemployed and poor.

New problems in the field of public health are constantly arising. As recent examples may be mentioned the outbreak of epidemic encephalitis in St. Louis, the identification of Rocky Mountain spotted fever of the eastern type, along the Atlantic seaboard of the United States, and the recognition of parrot fever, or psittacosis, as an endemic disease among birds of the parrot family in certain sections of the Pacific coast. Constant efforts are required for the detection and prevention of new dangers to the public health that arise from time to time.

One of the most important functions of the federal government in connection with public health is the conduct of scientific investigations for the purpose of devising new methods for preventing disease and ascertaining the importance and extent of new problems as they arise.

Boston Health Units—The fascinating story of the development of a chain of 7 Health Units in Boston, 1924–1933, is told in a compact volume of 71 pages, beautifully illustrated by many pictures, graphs, and floor plans. In carefully prepared text, Dr. Charles F. Wilinsky, whose association with the Health Unit movement from its inception is well known, traces this movement and indicates its significance to Boston.

The advantages of bringing health services to the doors of the community were significant. The need for coördinating and interrelating services was self-evident, and out of this philosophy evolved the real health center movement, which is about *two decades* old.

It would appear that the health needs of congested areas and improvement in general health can be best met by the decentralization of health work, by the interrelationship of essential activities, the mutual sharings of responsibilities, and the making available, in most convenient and accessible form, of sound health programs. This cannot help but result in furthering general health improvement and in the material reduction of illness. In the extension of this development the medical profession must, and we hope will, play a leading part.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Cancer Increase Stopped?—Study of the cancer death records in Massachusetts from 1900 to 1932 shows that the trend of mortality in that state is changing with the curve flattening and a slight decrease occurring among females. The authors believe the improvement is due to the drive against cancer, the changes in composition of the foreign population, and to the possibility that the saturation point is being reached.

BIGELOW, G. H., and LOMBARD, H. L. Change in the Massachusetts Cancer Trend. *New York State J. Med.* 210, 10:526 (Mar. 8), 1934.

Caring for Handicapped Children—The child handicapped by defects of hearing, vision, speech, and body should be given special consideration in any acceptable public program of health and education.

CARTER, M. M. The Handicapped Child. *Pub. Health Nurs.* 26, 3:123 (Mar.), 1934.

Progress (?) in Health Examinations—In a group of 8,758 families surveyed, about 2 per cent of the population over 20 years of age had a "health" examination during the twelve-month period, and less than 4 per cent had a medical examination of any kind. More women than men submitted to examination and the majority of both sexes were among the better-to-do. Twice as many of those who were sick 3 or more times during the period had a so-called "health" examination as of those who had not been ill. The author concludes:

It may be said that at present the "annual health examination" exists more in theory than in fact.

COLLINS, S. D. Frequency of Health Examination in 9,000 Families, Based on Nation-Wide Periodic Canvasses 1928-1931. *Pub. Health Rep.* 49, 10:321 (Mar. 9), 1934.

Ultimate Life Expectancy—The expectation of life for white males in the original registration area having increased from 48 in 1900 to 59 in 1930, with females showing a 3-year advantage along the line, by a most interesting process of reasoning the authors construct a hypothetical ultimate expectation of life. At birth it will be 69.6 years.

DUBLIN, L. I., and LOTKA, A. J. The History of Longevity in the United States. *Population*, 1, 2:15 (Feb.), 1934.

What Alaskan Natives Die of—More than a third of all native Indian and Eskimo deaths in Alaska are due to tuberculosis. Poor economic and hygienic conditions, ignorance, superstition, and transport difficulties tend to make tuberculosis eradication difficult, tedious, and expensive.

FELLOWS, F. S. Mortality in the Native Races of the Territory of Alaska with Special Reference to Tuberculosis. *Pub. Health Rep.* 49, 9:289 (Mar. 2), 1934.

A Sound Tooth Doesn't Decay—Convincingly summarized here is our present-day knowledge of the rôle of nutrition in building and preserving teeth free from caries.

GARLAND, J. Dental Health: A Problem in Nutrition. *New Eng. J. Med.* 210, 11:563 (Mar. 15), 1934.

Persuading Under-Weights to Eat—

It appears that gaining depends not on the selection of the diet, the preparation of the food, or particularly on the use of high calorie foods, but rather on the creation of the mind to eat.

The devices successfully used to persuade boys to eat up to 5,000 calories of food are discussed.

HORAN, T. N. Diet Table in a Private Boarding School of 200 Boys. *J.A.M.A.* 102, 11:836 (Mar. 17), 1934.

Manitoba's Maternal Mortality—A 5-year survey of 364 maternal deaths revealed findings similar to those from other American communities: abortions contributed nearly a fifth of the deaths; operative interference and faulty technics, as usual, increased the risk. Deaths from liver and kidney complications occur most frequently (and should be preventable). Sepsis, next in importance, also caused more than a quarter of all deaths.

JACKSON, F. W., *et al.* A Five-Year Survey of Maternal Mortality in Manitoba, 1928-1932. *Canad. Pub. Health J.* 25, 3:103 (Mar.), 1934.

Canadian Municipal Health Expenditures—Showing in table form the per capita expenditures for health administration in 16 cities, and dividing into percentages of the total the amounts spent for the various services, the study reveals many interesting comparisons.

JENKINS, R. B. Municipal Health Expenditures in Canada. *Canad. Pub. Health J.* 25, 3:120 (Mar.), 1934.

Milk Bottle Tops—Incredible as it may seem, 2 caps on a milk bottle keep out more contamination than 1 cap.

McFARLANE, V. H., and WEINZIRL, J. The Protective Value of the Single and the Double Cap for Bottled Milk. *Am. J. Hyg.* 19, 2:521 (Mar.), 1934.

Food Handlers and Dysentery—*Endamoeba histolytica* cultures smeared on fingers in excess of any amount with which even the most careless carrier would likely contaminate them, failed to survive drying by more than 10 minutes. This seems to invalidate the suggestion that most infections are spread through direct transfer from hands to food.

SPECTOR, B. K., and BUKY, F. Viability of *Endamoeba histolytica* and *Endamoeba coli*. *Pub. Health Rep.* 49, 12:379 (Mar. 23), 1934.

Relationship of Brucelliasis and Undulant Fever—To control and eradicate undulant fever in man, brucelliasis must first be eradicated in domestic animals: so concludes this paper.

STARR, L. E. Undulant Fever. *J.A.M.A.* 102, 12:902 (Mar. 24), 1934.

Toxoid and Toxin-Antitoxin—Toxoid with alum was more effective than without it, and both (in 2 doses of 1 c.c. given 1 week apart) were more effective than the conventional toxin-antitoxin in the hands of these research workers.

WHITE, J. C., and SCHLAGETER, E. A. Diphtheria Toxoid. *J.A.M.A.* 102, 12:915 (Mar. 24), 1934.

Tobacco and Alcohol—Neither the use of, nor the abstinence from, tobacco or alcohol plays an important rôle in the genesis of angina pectoris. In occasional cases, tobacco apparently aggravates attacks; in a few others, alcohol seems to prevent or relieve attacks.

WHITE, P. D., and SHARBER, T. Tobacco, Alcohol and Angina Pectoris. *J.A.M.A.* 102, 9:655 (Mar.), 1934.

Why Public Health Nursing Succeeds—Public health nursing services have been improved and extended to more and more of those who are in need of them, while other health services have been curtailed and emasculated. The reasons why are illuminating. This is 1 of 4 stimulating papers that go to make up an informal symposium on social medicine.

WINSLOW, C.-E. A. Nurses Show the Way. *Survey Graphic.* 23, 4:156 (Apr.), 1934.

PUBLIC HEALTH WITH THE CIVILIAN CONSERVATION CORPS WORK CAMPS

A GREAT deal has been written in the daily press and in various journals published in this country in regard to the many social advantages accruing from the Civilian Conservation Corps project, but little has been said in regard to its influence upon public health.

By the time this project has faded away into the limbo of past deeds, nearly one million young men throughout the country will have been enrolled in this work for varied lengths of time, averaging 6 months for each. What has happened to them?

In the first place, before enrollment, they were given a simple physical examination, which showed them, particularly, the great necessity of caring for their bodily ills. They were then sent to work camps throughout the country to live and labor for a 6-months period. As these camps were established by the Army, they all had a family resemblance. This resemblance was particularly noted in the preparation and care of food, establishment of proper latrines and baths, provision of a safe water supply, and proper housing and recreation.

Before going further, attention is called to the fact that most of these young men came from a class in society which, in many cases, due to financial reasons, living conditions were not up to the standard which is considered proper for people of this day and age, and a great many of the requirements covering living conditions were very new to the enrollee.

The food provided was of the same standard furnished the Army and the variety allowed by Army ration tables was required. Great care in the selection and training of cooks was exercised; ample bathing facilities with compulsory bathing was the rule; latrines were built fulfilling the most approved sanitary requirements and cleanliness in these latrines was kept at the highest point. All water supplies were checked by laboratory examination and where necessary they were chlorinated or otherwise purified. The barracks were required to be kept clean, and ample ventilation was provided.

In some localities, Civilian Conservation Corps camps were exposed to malarial infection. In addition to limiting the number of cases occurring among these men, careful studies of malaria prevention have been made and anti-malarial work of considerable magnitude has been conducted. The final eradication of malaria is, of course, a utopian dream, but everything that can be done toward the advance in the knowledge of this disease and its prevention is of great value, and it is believed that the information obtained by the study at these camps has advanced the knowledge of malaria prevention and control. Disease conditions of all kinds have also naturally received close attention, and it is not believed that any concentration of men doing work of this character has received as much care and attention from a medical standpoint as has been bestowed upon the Civilian Conservation Corps.

Will this affect the future lives of these young men? This is considered a certainty. Youths of this age are both curious and imitative. They are curious to find out why various precautions are taken, and they are so imitative, that when they return to their homes, they will desire to put into effect what they have learned in regard to hygiene and sanitation. How do we know this?

You have only to visit hundreds of towns, villages and hamlets in this country, and by investigation find that the most active proponents of improvements of hygiene and sanitation in the community are frequently ex-soldiers. Though the Civilian Conservation Corps enrollee is not a soldier in any sense and is not treated as a soldier, the hygienic precautions instituted in these camps are essentially those used in Army service and the effect on the individual is about the same. Is this project of value to the public health of the country? Undoubtedly so, and the results from that standpoint alone will be incalculable.

MEDICAL SENSATIONALISM IN THE PRESS

UNDER this heading is an eminently sound and much needed editorial.¹ It was elicited by the misquotation of Dr. James Ewing, than whom there exists no more eminent authority on cancer in the United States. He was quoted as saying that the idea of discovering a cure for cancer is absurd, whereas his point was that a single cure for all types of cancers would never be found. He also spoke of the exposure of the skin to wind and to sunlight as a cause of cancer if carried to excess. His statement was used as a sensational attack on nudism! Of course Dr. Ewing made a protest, and on account of his position, was able to get it published.

Any careful reader can bring many instances of where scientific facts are changed to sensational misstatements. For example, a few years ago there appeared a statement, "Cure for typhoid found in sewage." The abstract of the article which followed was by one of our leading bacteriologists who had reported the finding in sewage of bacteriophage which was active against strains of typhoid.

Dr. Ewing properly says that such false reports unsettle the minds of the public and fill sufferers with doubt and with fear. The writer of the editorial suggests that if every piece of medical sensationalism and yellow medical journalism brought a storm of criticism from the doctors of the community, reporters and editors would be more careful in what they wrote and published. This may be true, but our own experience leads us to doubt it. The success of certain authors who have written popular books in a sensational manner on medical

subjects is our reason for the doubt. However, we are not trying to discourage the idea of showing up such misleading journalism. We have found repeatedly that even where carefully typewritten statements on medical subjects are given to newspapers, many of them persist in making of them what they call a "story." There is no doubt that they like to be sensational, and many of them have a perverted idea of what makes real news. Even journals published as laboratory practice by schools of journalism do this.

On the other hand, we owe much to the press for spreading information concerning new discoveries in medicine and the results which are responsible for the tremendous prolongation of life and the great lessening of contagious diseases.

REFERENCE

1. *New York State J. Med.*, 34, 1:25 (Jan. 1), 1934.

TOWARD MORBIDITY REPORTING

GOOD public health work rests upon good practice of medicine rather more than upon any of the other collaborating professions, arts and sciences.

Accuracy and clarity of diagnosis are essential to any thorough comprehension of the amount and variety of disease entities and symptom complexes which affect mankind. One influence of great power in raising the level of medical thinking, and making comparable the results of clinical observations of physicians with widely differing experiences, is the adoption of a national nomenclature of disease. Such systems of names of diseases and conditions are in use in the Krankenkassen services of Austria and Germany, and, as recently revised, by the Royal College of Physicians in England.

For the United States we have the *Standard Classified Nomenclature of Disease* which is already influencing the teaching and recording of medical and surgical conditions throughout the United States.

One hundred and eleven of the most influential hospitals are using it exclusively, and these include the teaching hospitals at Harvard, Yale, Cornell, University of Pennsylvania, Western Reserve, Rush, Nebraska University, Stanford University, Vanderbilt University, and Tulane medical schools. In some 300 other hospitals this scientifically constructed, all inclusive system of listing diseases or pathological conditions by anatomical site and etiology is in use. These include hospitals for mental disease, tuberculosis hospitals, and one of the great hospitals for communicable diseases, the Herman Kiefer Hospital of Detroit.

Health officers, registrars and other vital statisticians have a large stake in the extension of accurate knowledge of the prevalence of disease of all kinds, which can come about only when there is a uniformity in the naming of sicknesses equivalent to that of the *International List* in describing the causes of death.

Opposite each of the thousands of names of disease conditions in the *Standard Nomenclature* is the number of the cause of death according to the *International List* under which the registration would be made if the patient died. Thus we have the structural provision for case mortality rates according to the list of death causes now universally used by modern nations.

A second edition of the little pocket volume *A Standard Nomenclature of Disease* is already needed and is in preparation. Administrators of health services should feel it an obligation to see that in all listing of disease, whether preventable or not yet known to be so, the standard nomenclature be in effect in clinics, hospitals and sanatoria under their direction.

ASSOCIATION NEWS

SIXTY-THIRD ANNUAL MEETING

PASADENA LOCAL COMMITTEE

J. D. Dunshee, M.D., *Chairman*
Louise Dimmitt, *General Secretary*

EXECUTIVE COMMITTEE

Chairman: J. D. Dunshee, M.D., Director, State Department of Health
A. E. Clifton, Superintendent of Schools, Los Angeles County
Dr. J. Rollin French, President, Western Hospital Association, Los Angeles
Dr. L. L. Henninger, President, Pasadena Branch, Los Angeles County Medical Society
C. C. Hine, Chairman, Health and Sanitation Committee, Los Angeles Chamber of Commerce
Roger Jessup, County Supervisor, Los Angeles County
Dr. Carroll W. Jones, Los Angeles County Dental Society
Dr. Sven Lokrantz, Director of Health, Los Angeles City Schools
Dr. Edward M. Pallette, California State Board of Health
Dr. George Parrish, Los Angeles City Health Officer
Dr. J. L. Pomeroy, County Health Officer, Los Angeles County
Dr. F. M. Pottenger, Past-President, American College of Physicians
Dr. W. B. Wells, Commissioner of Health, County and City of Riverside

ENTERTAINMENT AND RECEPTION COMMITTEE

Chairman: Arthur K. Wyatt, Pasadena Health Department

MEETING ROOMS COMMITTEE

Chairman: Ernest Tew, Chief Inspector, Pasadena Health Department

LADIES ENTERTAINMENT COMMITTEE

Chairman: Mrs. Philip Schuyler Doane, President, Women's Auxiliary, California State Medical Society

PUBLICITY COMMITTEE

Chairman: Mrs. Alma Overholt, Publicity Manager, Catalina Island Company

REGISTRATION AND INFORMATION COMMITTEE

Chairman: Robert H. Snyder, Manager Convention and Publicity Department, Pasadena Chamber of Commerce

INSPECTION TRIPS COMMITTEE

Chairman: Walter S. Mangold, Chief, Division of Sanitary Instruction, Los Angeles County Health Department

NEW YORK, CHICAGO AND ALL POINTS WEST! ALL ABOARD!

SO you are going to Pasadena to attend the Sixty-third Annual Meeting! Are you also planning to accept the invitation presented by the Northern California Public Health Association and visit San Francisco, Stockton, and Sacramento afterwards?

To make it easy and inexpensive for you to do both, the Association is sponsoring an all-expense, conducted

tour, so planned as to permit members from almost every section of the country to join it at a convenient point. A preliminary announcement of the tour was made to the membership some weeks ago, and the response was enthusiastic. An illustrated, day-by-day itinerary is in preparation, which will be mailed early in May. Train schedules are included, complete costs

of the tour from many points, and as full a description as it is possible to give of what you will do and what you will see and how you will be entertained if you join the group.

Remember that the dates of the Annual Meeting are September 3-6. Late August and early September make an ideal vacation period; the all-expense tour will cost you less, and you will receive infinitely more for your money than if you traveled alone and made your own arrangements. Remember, too, that your family and friends may come. Let the tour and the Annual Meeting constitute your vacation for this year. Watch for the printed announcement, and make your plans to climb aboard the A.P.H.A. Special at the proper time.

PASADENA ANNUAL MEETING PROGRAM

APRIL 1 was the date set by the Program Committee for the receipt of preliminary Section programs for the Pasadena sessions. Though the material is still tentative in form, it can be announced that it is impressive.

Here is a figurative handful from the program bag:

A dinner under the auspices of the Committee on Professional Education.

The Monday evening General Session at which Dr. Haven Emerson will present his Presidential address.

A public meeting Tuesday evening under the auspices of the Western Branch.

The Annual Banquet on Wednesday evening. Dr. F. W. O'Connor has been invited to present the leading address.

A session of the Health Officers Section on "Serving the Public for Health," with Dr. Henry F. Vaughan and Dr. J. L. Pomeroy as the principal speakers.

A luncheon session devoted to papers and discussions on diphtheria.

A symposium on amebic dysentery. Symposia on Health Hazards in the

Oil Industries, in the Smelting and Refining Industries; Typhoid Outbreak in Southern California; Dairy and Milk Products; Selling Health Department Members First on Health Education; Food Products; Water and Sewage; Diagnostic Procedures and Reagents; Health Education in Schools and the Community at Large; The Part of the Public Health Nurse in the Epidemiology of Syphilis, etc.

FROM 450 SEVENTH AVENUE TO 50 WEST 50TH STREET

RECENT letters from Association headquarters carry a new address—50 West 50th Street—some of the discerning perhaps have noticed. The cover of the April *Journal* records it for the first time.

The organizations in the National Health Council, of which the American Public Health Association is one, were housed for ten years at 370 Seventh Avenue. This address became universally familiar as national health headquarters. In 1931 they moved to 450 Seventh Avenue, and now they are all together at 50 West 50th Street, which is one of the buildings in the extensive development known as Radio City or Rockefeller Center.

The Association extends a warm invitation to all members visiting New York to call at the new offices.

CLOSING DATE FOR ACCEPTING APPLICATIONS FOR FELLOWSHIP

ACTIVE members who wish to make application for Fellowship in the American Public Health Association, are hereby notified that their applications must be submitted to the Committee on Fellowship and Membership not later than July 1, 1934, if final action is to be taken by the Governing Council at the Pasadena Annual Meeting in September.

For the benefit of the newer members of the Association, the two pre-

requisites for applying for Fellowship are repeated here. These are (1) the applicant must have been an active member of the A.P.H.A. for at least 2 years, and (2) he or she must be at least

30 years of age. The professional qualifications which are essential are given in the By-laws, which appear on page 13 in the *Year Book* issued as a supplement to the February *Journal*.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

James W. Barkley, M.D., Belzoni, Miss.,
County Health Officer
Ralph E. Brodie, M.D., 1 East Park St.,
Albion, N. Y., Health Officer
T. O. Coppedge, M.D., Nashville, N. C., Nash
County Health Officer
L. Edward Cotter, M.D., Red Hook, N. Y.
(Assoc.)
Gilbert D. Forbes, M.D., Kendall, N. Y.,
Health Officer
Ulysse Forget, M.D., 15 Miller St., Warren,
R. I., Health Officer
Harry H. Griffith, Conemaugh, Pa., Health
Officer
Thomas B. Joyce, M.D., 925 First St.,
Peekskill, N. Y., Taking Extension course
for Health Officers, Grade II.
Andrew J. Krog, Board of Health, Plainfield,
N. J., Health Officer
Elroy F. McIntyre, M.D., Santa Fe, N. M.,
City and County Health Officer
Ray E. Persons, M.D., Cairo, N. Y., Health
Officer
Ralph S. Pickett, M.D., Olcott, N. Y., Health
Officer, Town of Newfane
Harry S. Rosenberg, M.D., Franklin Square,
L. I., N. Y., Health Officer, South Floral
Park
George H. Schenck, M.D., Southampton, N.
Y., Health Officer
Isidore Schnap, M.D., Box A, Kings Park,
N. Y., Taking Extension course for Health
Officers, Grade II.
Richard O'B. Shea, M.D., Welfare Bldg.,
Bridgeport, Conn., Health Officer
Stanley A. Stealy, M.D., Box 307, Grayling,
Mich., Four County District Health
Director
James B. Vaughn, M.D., Castlewood, S. D.,
Superintendent, Hamlin County Board of
Health
Raymond A. Vonderlehr, M.D., U. S. Public

Health Service, Washington, D. C., Passed
Assistant Surgeon, Division of Venereal
Diseases

Laboratory Section

Charles F. Craig, M.D., School of Medicine,
Tulane University, New Orleans, La.,
Professor of Tropical Medicine; Head, De-
partment of Tropical Medicine
Jessie E. Dow, 503 Hudson Ave., Albany, N.
Y., Senior Bacteriologist, State Dept. of
Health
Malvina M. Grieves, R.N., City Hospital,
Jamestown, N. Y., Science Instructor,
School of Nursing
Rexford Hansen, 1450 W. Marquette Rd.,
Chicago, Ill., Director of Clinical Labora-
tory
Warren A. Kramer, 5341 Goodfellow Ave.,
St. Louis, Mo., Senior Chemist, Water
Purification Plant
William D. Leech, Cooranbong, N. S. Wales,
Aust., Director, Australasian Food Research
(Assoc.)
Edna Lemon, 2300 Carson St., Torrance,
Calif., Bacteriologist, Los Angeles County
Health Dept.
Elizabeth A. Lockwood, 75 Carnegie Ave.,
East Orange, N. J., Senior Technician, and
Instructress in Clinical Pathology, Essex
County Isolation Hospital
Arthur B. Massey, Blacksburg, Va., Instructor,
Dept. of Botany and Plant Pathology,
Virginia Polytechnic Institute
Raymond L. Pierce, 252 Putnam Ave.,
Hamden, Conn., Director of Laboratory,
Brock-Hall Dairy
H. B. Richie, B.S., 8215 S. Throop St.,
Chicago, Ill., Chemistry Laboratory, Swift
& Co.
Harold C. Robinson, Ph.D., General Hos-
pital, Geneva, N. Y., charge of Ontario
County Laboratory

Virginia M. Ryan, 67 N. Cowley Rd., Riverside, Ill., Research Bacteriologist, State Dept. of Health

Armin V. St. George, M.D., 19 West 55 St., New York, N. Y., Assistant Director, Dept. of Hospitals, City of New York

Harry J. Sears, Ph.D., Univ. of Oregon Medical School, Portland, Ore., Professor of Bacteriology and Public Health

Jessie E. Stickel, Univ. of California Hospital, San Francisco, Calif., Bacteriologist

Marion E. Stroud, 1623 W. Washington St., Phoenix, Ariz., Bacteriologist, State Laboratory

Vital Statistics Section

Alice I. Alford, B.A., 505 N. Carroll St., Madison, Wis., Secretary to Director of Vital Statistics, State Board of Health

A. Glenn Evans, 189 Dwight St., New Haven, Conn., taking course for C.P.H. degree (Assoc.)

Floyd M. Feldman, M.D., 615 N. Wolfe St., Baltimore, Md., Rockefeller Foundation Fellowship, Johns Hopkins; formerly with Minnesota State Dept. of Health

Bettie C. Freeman, Sc.D., Dalhousie Univ., Halifax, N. S., Canada, Statistical Assistant, Dept. of Preventive Medicine

Maurice L. Goldstein, Met. Life Ins. Co., 1 Madison Ave., New York, N. Y., Manager, Tabulation Section, Statistical Bureau

Eva W. Ramsey, 130 Capitol Bldg., Salt Lake City, Utah, Deputy State Registrar of Vital Statistics

Elizabeth J. Steele, 28 E. 28 St., New York, N. Y., Special Research Clerk, Statistical Bureau, Metropolitan Life Ins. Co.

Robert J. Vane, Metropolitan Life Ins. Co., 1 Madison Ave., New York, N. Y., Supervisor, Occupational Rating, Statistical Bureau

Public Health Engineering Section

James D. Caldwell, Health Dept., Murfreesboro, Tenn., Sanitary Officer, Rutherford County Health Dept.

Anselmo F. Dappert, State Dept. of Health, Albany, N. Y., Principal Sanitary Engineer

Nelson Hall, Saginaw County Health Unit, Saginaw, Mich., Sanitary Inspector

Albert I. Howd, State Dept. of Health, Albany, N. Y., Sanitary Engineer

Edwin W. A. Humphreys, C.E., Humglas House, Carlisle Place, Westminster, London, S.W. 1, England, Design of Waterworks (Assoc.)

Samuel B. Morris, 319 City Hall, Pasadena, Calif., Chief Engineer, City Water Dept.

George W. Schusler, 120 Ruskin Ave., Pitts-

burgh, Pa., Superintendent Engineer, Dept. of Health

Herbert H. Wagenhals, State Dept. of Health, Albany, N. Y., Associate Sanitary Engineer

Industrial Hygiene Section

John P. Boroszewski, M.D., 351 Abbott Rd., Buffalo, N. Y., Medical Director, National Aniline and Chemical Co.

Willard F. Machle, M.D., Kettering Laboratory, Univ. of Cincinnati, Cincinnati, O., Assistant Director

Food and Nutrition Section

Helen S. Butler, B.S., 414 Goodwyn Institute Bldg., Memphis, Tenn., Director, Memphis Dairy Council of Tennessee

Edwin J. Cameron, Ph.D., 1739 H St., N.W., Washington, D. C., Bacteriologist, National Canners Assn.

Culver S. Ladd, B.S., Box 653, Bismarck, N. D., State Food Commissioner

Leicester Patton, B.S., 623 City-County Bldg., Pittsburgh, Pa., Superintendent, Bureau of Food Inspection, Dept. of Health

Robert W. Pilcher, Ph.D., 306 N. 5th Ave., Maywood, Ill., Supervisor, Nutrition Laboratory, American Can Co.

Rachael L. Reed, 914 U. B. Bldg., Dayton, O., Director, Miami Valley Dairy Council

Child Hygiene Section

J. Warren Bell, Ph.D., M.D., 629 Main St., Olean, N. Y., Director, Bureau of Child Hygiene, Cattaraugus County Dept. of Health

Public Health Education Section

Dr. Roger L. Hickman, State Sanatorium, Clinton, Okla., Medical Director, State Institution for the Tuberculous

Lucy S. Morgan, B.A., 2424 Kingston Pike, Knoxville, Tenn., Assistant in Health Education Project, Univ. of Tennessee

Mrs. Charles W. Pollard, 301 S. Happy Hollow Blvd., Omaha, Nebr. (Assoc.)

Dr. Edward H. Skinner, 1532 Professional Bldg., Kansas City, Mo., President, Health Council

Epidemiology Section

Arthur H. Cummings, M.D., State Office Bldg., Buffalo, N. Y., Assistant District State Health Officer

W. Palmer Dearing, M.D., 54 Aerial St., Arlington, Mass., Assistant in Epidemiology, Harvard School of Public Health

Philip J. Rafle, M.D., State Dept. of Health,

Albany, N. Y., Assistant District State Health Officer

Unaffiliated

Lynn Dodge, M.D., 11 Pleasant St., Fairport, N. Y. (Assoc.)

Anne P. Schumacher, B.A., 235 E. 12 St., New York, N. Y., Instructor in Public Health, Hunter College

Public Health Nursing Section

Vera Klingman, R.N., 11 S. First East, Logan, Utah, Health Supervisor, City Schools
Katherine Rickan, R.N., 5219 Drexel Ave., Chicago, Ill., Supervising Field Nurse

Associate Member requesting Active Membership

Paul R. Burroughs, M.D., Director of Health, Santa Monica City Schools

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

American National Red Cross

Courses in Teacher Training for Home Hygiene Instructors:

University of California, Los Angeles, Calif.—June 29–August 10

Colorado Agricultural College, Fort Collins, Colo.—July 7–August 17

Pennsylvania State College, State College, Pa.—July 2–August 10.

Syracuse University, Syracuse, N. Y.—July 2–August 10

The National Society for the Prevention of Blindness, 50 West 50th St., New York, N. Y.

Courses to prepare teachers for the education of children with seriously defective vision:

University College, University of Chicago, Chicago, Ill.—June 20–July 27

University of Cincinnati, Cincinnati, Ohio—June 25–July 31

State Teachers College, Buffalo, N. Y.—July 2–August 10

Teachers College, Columbia University, New York, N. Y.—July 9–August 17

University of California, Berkeley, Calif.

June 25–August 3

Elementary Epidemiology
Elementary Public Health

(The above courses are offered in our Inter-session, May 14–June 22)

General Bacteriology
Child Development and Training
History of Nursing
Principles and Practice of Public Health Nursing

Columbia University

DeLamar Institute of Public Health, College of Physicians and Surgeons, New York, N. Y.

June 12–30

School Health Supervision—Medical Inspection, Mental Hygiene, Hygiene and Health Education, and Physical Education.

Teachers College, New York, N. Y.

July 9–August 17

Administration of Health Education in Public Schools
Child Hygiene
Health Education
Health and Physical Education
Health Care of Infants
Home and Community Hygiene
Nutrition and Health
Personal Hygiene
Public Health Nursing
Public Health Administration
Safety Education
School Nursing

Sight Saving Classes
Social Hygiene
Teaching Lip-Reading

Cornell University, Ithaca, N. Y.
July 9-August 17

Gymnastics and Dancing
Health Supervision of School Children
Hygiene of the School Child and Adolescent
Measurements of School Children
Physical Education
Principles of Health Education

Duke University, Durham, N. C.
June 8-August 10

Materials and Methods in Health Education
Materials and Methods of Physical Education
Personal and School Hygiene

NORTHERN CALIFORNIA PUBLIC HEALTH
ASSOCIATION

THE Northern California Public Health Association at its meeting on March 17 in Stockton, elected the following officers:

President—Professor Leon B. Reynolds
President-elect—Dr. J. C. Geiger
Vice-President—Helen Hartley, R.N.
Treasurer—Mary E. Davis, R.N.
Secretary—Dr. I. O. Church
Representative to the Regional Council of the Western Branch—Dr. Frank Kelly
Representative to the Governing Council, A.P.H.A.—Dr. Herbert F. True

SOUTHERN CALIFORNIA PUBLIC HEALTH
ASSOCIATION

THE following officers were elected at the meeting of the Southern California Public Health Association on March 7:

President—Charles W. Decker, M.D.
President-elect—J. D. Dunshee, M.D.
First Vice-President—A. M. Lesem, M.D.
Second Vice-President—R. C. Main, M.D.
Secretary-Treasurer—C. G. Wharton, M.D.
Representative to Governing Council, A.P.H.A.—William B. Wells, M.D.

CONGRATULATIONS TO DR. WELCH

ON April 8, Dr. William H. Welch celebrated his 84th birthday; and April 7 was the 50th anniversary of his connection with Johns Hopkins University. He became Professor of Pathology in that university April 7, 1884.

COLONEL THEODORE ROOSEVELT ELECTED
PRESIDENT OF NATIONAL HEALTH
COUNCIL

COLONEL Theodore Roosevelt was recently elected President of the National Health Council, succeeding William F. Snow, M.D., F.A.P.H.A., who has held that office since 1927.

FULLER & MCCLINTOCK MOVE

FULLER & McClintock on April 30, moved their engineering offices from 170 Broadway, where they have been

located for nearly 30 years, to larger and specially planned quarters in the Park-Murray Building, 11 Park Place, New York, N. Y.

PERSONALS

DR. J. D. DUNSHEE, F.A.P.H.A., of Pasadena, has been appointed Director of the State Department of Health of California. Dr. Dunshee is Chairman of the 1934 Annual Meeting Local Committee.

BRIGADIER GENERAL M. A. DeLANEY, Assistant Surgeon General, U. S. Army, member A.P.H.A., was selected by the University of Pennsylvania Club, New York, as the most outstanding graduate of the University for the year 1934, and was awarded the Guggenheim Honor Cup at a banquet at the Club on March 22. General DeLaney is in command of the Medical Field Service School, Carlisle Barracks, Pa. He is a member of the Delta Omega Society, and many public health organizations.

JAMES A. DOULL, M.D.C.M., Dr.P.H., F.A.P.H.A., Professor of Hygiene and Public Health of the Western Reserve University School of Medicine, Cleveland, O., has been elected an Honorary Fellow of the Royal Sanitary Institute of England.

DR. WADE HAMPTON FROST, F.A.P.H.A., has retired as Dean of Johns Hopkins School of Hygiene and Public Health, effective in July when his term expires. Dr. Allen Weir Freeman, F.A.P.H.A., Professor of Public Health Administration at the school since 1923, has been named to succeed him.

DR. WILLIAM H. BEST has been appointed Deputy Commissioner of Health of New York City. He has been associated with the Health Department for 18 years.

Organization of Adult Groups for Health Education^{*}

MARY P. CONNOLLY, F.A.P.H.A.

Director, Division of Health Education, Department of Health, Detroit, Mich.

ALL Americans are "belongers," says George Bernard Shaw, as he pictures even the smallest hamlet with most of its citizens leaving offices, wash tubs, and ploughing to dash off to meetings. Mr. Shaw's opinion offers much encouragement to those who are new in the field of health education. It provides disappointment for those who accept it as a working plan for spreading health information.

Organized groups pave the way for many health advances. This is particularly true when the group sponsors a movement and continues to give it support. If large numbers of persons were affiliated with groups, the problem of disseminating health information through such groups would be simpler. However, a careful analysis of any given community will reveal that the rank and file of citizens do not hold continuous membership in any organization. Americans sample many new enterprises, but the turnover is such that it is a mistake to feel that we have influenced the community with a message

if we have reached only the organized groups. Professional organizations, churches, and those carrying insurance benefits are the only ones that can claim fairly continuous membership.

I believe it is a mistake to assume that those who belong to organizations necessarily are leaders and will be forces in disseminating material given to them. Many persons join clubs or societies because their friends belong or because there appears to be a social advantage in such membership. Responsibility for the undertakings of a society is not always shared by all of its members. There is no doubt that we should include organized groups in any plan for community health education, but they should be only one unit. It is apparent that the bulk of the population which we must reach is not waiting and ready to receive us or our message.

If it is important that the newer knowledges of disease prevention and health education be presented just how shall we go about doing this job?

Every program which aims to change the behavior of individuals may well be built upon 3 separate steps: research, publicity, and direct contact. It is a foregone conclusion that those who deal with health education will not formu-

^{*} Read before the Public Health Education Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

late a program without the benefit of research. In our early days, which were missionary in character, we put tremendous zeal into some programs for which we feel apologetic today. We believe we are doing better.

Publicity paves the way; but it does not do more than that. Adults change their habits only after discussion and deliberation. This is a protection because if we changed our habits as a result of the barrage of written and spoken material which descends upon us from radio and newspaper, we would be in a state of confusion confounded, from which we would derive neither health nor comfort. Publicity is important because it draws attention to subjects which need thought. Thinking does precede a rational change of habits in adults. Since most persons have not sufficient background for thinking through many problems in health behavior, they must have personal help in making their decisions.

Personal health advice should come from a physician who knows the individual, his capacities and tendencies. The physician who wishes to practise preventive medicine will have to assume this responsibility if large numbers of persons are to go to him to learn to keep well. It frequently requires much persuasion to convince a man that he needs to go to a physician when he is not ill. It is disappointing to the man when he does not receive advice with his health examination.

In addition to personal health advice it is important in this day of too close living that men and women shall learn something about disease communication and how they may safeguard themselves; something of the principles of sanitary science, if only for esthetic reasons; something about child care and behavior which will give their children a better chance. This intensive education must come from a person who has the time and training to present the ma-

terial in a way in which it may be understood and from which profit will come to the student.

I believe the psychologists have convinced us that if we wish to gain anyone's attention we must start with a recognition of his interests. We can hope to do no better than to hitch our program to the van of interests which carries one's activities.

How shall we know a person's interests? How shall we go about gathering people into numbers which we can reach at a minimum of expense?

In answer to this first question, it is necessary that the person responsible for health education go about among many groups, even when the interests of the groups are not remotely connected with health promotion. This is the only means by which we can learn how the average person thinks and feels. When the timid looking little woman who sits next to you as a member of a group tells you of the health needs of young mothers in her neighborhood, and you can offer her a plan for intensive education for these mothers if she will bring them together, you have made group organization simple; and while your students are being brought together by the interested woman you can go on to claim the attention of other such leaders. The going about should be purposeful on the part of the health educator, in order that all classes will be met.

A study of the community should be made each year to enable the person responsible for the program to determine in which sections effort should be concentrated. If accurate records are kept this is not a difficult matter.

Large numbers of persons must learn to know those who provide health information and to know them well enough to include them in their programs. It may seem a waste of time to serve on a committee which desires to erect a monument to a famous citizen

or to abolish hideous sign boards; but in no other way is it so easy to gain the attention of those who influence public opinion.

This method of organization has a number of points to commend it. The person who asks for health education for a particular neighborhood assumes responsibility for the group. It is the plan of an individual who is proud of it and rarely fails to hold the group together. Each person who joins the group is visited and interested by one who is a neighbor. The education is something for which the group has asked and not a plan imposed upon them by a benevolent municipal or private organization.

Progressive women in churches form many interested groups on a basis of their particular needs. The leader of a cradle roll may ask for a series of lessons on infant care, while the superintendent of a Sunday School will invite parents of older children who wish to learn about communicable disease or child behavior.

Evening schools provide us with a means of incorporating health information in the course of study given to adults who wish to learn to read, write, speak English, or to finish elementary school. In addition to the regular evening classes, extension classes are frequently provided for groups of women unable to go to the regular schools. If the primary interest and need of the group is English, our health information becomes much more vital when it is incorporated in the driving need.

The unemployed who have had to wait for relief in public welfare stations have shown us how eager large numbers of men and women are to learn how to keep well. It is to be hoped that the opportunity for presenting health material to so many, who are ready and eager for it, will never again need to come in the same way. However, the

public health organization that has planned a series of health talks for the large groups who wait in relief stations, and courses to suit the needs of smaller groups that will come together for this purpose, has relieved dispirited men and women of some hours of despair and given them a fund of information which will carry over into better days.

Particular attention should be paid to food budgets and meal planning, the early discovery of tuberculosis, and protection against communicable diseases when persons receiving relief are met. It is wise to distribute those who wish further information among groups not receiving relief in order that a more normal approach may be made to problems which the person finds difficult to solve at the time because of lack of money.

The health educator who is a member of the local board of the Girl Scouts, the Camp Fire Girls, the Boy Scouts, or similar organizations has not only an opportunity for providing a health program for the organization, but through contact with parents and leaders may extend group instruction to adults who would not be contacted in any other way. A particularly successful form of group organization is attained when the program is shared with a psychologist or a recreation leader. Units of study, of which health is one, provide sufficient variety to hold the interest of the group. Here, too, the women are brought together by a friendly person who becomes a member of the class.

In any plan for community education for health it must be remembered that intensive education can be given to a relatively small number of persons. These persons must be made to feel that because of their additional knowledge they have a responsibility for spreading this knowledge to others who are not so well equipped.

Small groups like to feel that they

are a part of a larger movement—that they walk with many. Health guilds serve the purpose of binding groups together and provide a concerted effort in all parts of the city. The guilds are composed of women who have completed a course in health instruction. They meet at regular intervals of 1 or 2 months. A representative from the department of health presents a particular problem to the guild at the meeting, and the members assume responsibility for solving it among their immediate neighbors. This provides a continuation of interest in health matters and a channel for keeping large numbers of persons informed regarding new advances made in public health.

Information given to groups should lead to action. Communities may well expect that those who have received intensive education for health will be interested in seeing that the children of the neighborhood are vaccinated and protected against diphtheria, and that efforts will be made to direct those needing medical care to the regular place for receiving it. The organization providing the education will have the benefit of numbers of persons furthering its program in addition to its regular staff.

Marked differences can be seen in the health behavior of Negroes when large numbers of this race have been reached with specific health instruction. One guild composed of less than 400 women was responsible for the immunization of more than 9,000 Negro children under the age of 5 years. There was a distinct feeling of pride among these women for having been responsible for their own race. Through the efforts of these same women and a group of progressive Negro physicians, it is expected that at least 2,000 Negroes over 15 years of age will be given an X-ray of the chest this month, in an effort to eradicate tuberculosis among their people.

Race prejudices and inter-race en-

imities can destroy group interest. Race prejudices are avoided when groups come together because of mutual interests. Because a neighborhood is largely foreign born does not mean that all of its residents will see eye to eye on any given subject. Even within racial groups, habits and customs are so different that agreement on few subjects can be reached. If the family sympathies are with monarchists, the mother will not be likely to join with a neighbor whose homeland sympathies are liberal, even to learn how to care for her baby.

Stereotyped material never holds the interest of a group for any length of time. When a group is formed it is advisable to meet with it and to prepare lesson plans to satisfy its specific needs. The course prepared for a 12 week period may be divided into 4 units: community health, communicable disease, child hygiene, and home care of the sick. Units may be extended or contracted. Two hour class periods are usual, with half of the period allowed for group discussion which should be carefully guided by the instructor. The course in Home Hygiene and Care of the Sick of the American Red Cross is desirable for those who wish to work for a certificate.

The public health nurse who has had preparation for teaching is the person best fitted to conduct classes for health information. Because of her experience in the homes of many, she is able to understand the needs and limitations of those who come for instruction and the nursing technics which she is able to demonstrate are always a source of pride to the women who learn them. Definite skills which may be shown to a neighbor inspire respect for the information which accompanies them. Groups formed for the study of nutrition should be guided by a nutritional expert.

At present, women must form the large number of those who are given

intensive courses in health. Groups of men may be reached in factories, at luncheons, and at meetings for an occasional talk about important health matters, but organized classes which prepare for leadership can be given only to those who can devote a regular period each week for such education.

With the new leisure provided under recent legislation there is an opportunity for study courses for men who wish to know the health problems of their community. Groups of men should be taught by a man, and the new order is a challenge to men in public health which will have to be met.

Intensive group teaching offers the only means of personal contact with persons who because of their better economic status will not be met by the public health nurse in the home or will not be found in clinics in which conferences are held. This group of self supporting, independent folks fashion

the thinking of most communities. They own their homes; they pay taxes; they are vitally interested in what is provided for the health and welfare of their children. The greater number of these persons have had only such information as they obtained in physiology and hygiene courses in school, high school, or college. They have no means of interpreting the vast amount of so-called health information which appears in the press and is heard over the radio. Public health organizations can make a plan for keeping them informed as to the newer developments in health protection and conservation or they can be left to the winds which blow from bad advertising, cults, and fads. When community understanding is necessary to control disease or support legitimate health projects, the leader with sound information will be found to be of inestimable help in the health organization.

Switzerland—Physical Examinations of School Children

PHYSICAL examinations of school children were recently introduced in the rural districts in Switzerland with the coming into effect of the federal law on prevention of tuberculosis; the examinations were also extended to those city schools where they had not been given previously.

The school physicians in the rural districts serve on a part-time and in the cities on a full-time basis. The maximum number of children which it is considered advisable to allow to each physician is 3,000 in the rural districts and 8,000 in the cities.

In the cities the school children are given a tuberculin test and tested for the rapidity of sedimentation of the blood; those of them presenting sus-

picious symptoms are given a radiologic examination. In rural districts the regular school physician refers the suspicious cases to a specialist. All children in whom tuberculosis is found are referred to special dispensaries where the necessary measures are taken.

The school physicians are required to examine the teachers for tuberculosis. Those afflicted with a contagious form of this disease are given leave of absence with 80 per cent of their salaries. Supervision over the general hygiene of the school buildings is also a part of the physicians' work.—Office International d'Hygiene Publique, *Bulletin Mensuel*, Paris, Jan., 1934.

Transmission Sequence of Syphilis*

WILLIAM A. BRUMFIELD, Jr., M.D., and DUDLEY C. SMITH, M.D.

*Department of Syphilology and Dermatology, University of Virginia,
Charlottesville, Va.*

THE conditions under which syphilis is usually transmitted from one individual to another are simple and generally well understood. Based upon this knowledge reduction and control of the disease have been sought along several lines, particularly, (1) by education of young people in sex matters, urging continence, (2) by educating the incontinent in the use of prophylaxis, (3) by the suppression of commercialized prostitution, and (4) by extending clinical facilities so that the infected persons may seek treatment as early as possible. There are at present no convincing figures showing that these methods have brought about a material reduction in the incidence of the disease in the United States.

More recently, the U. S. Public Health Service through a grant from the Rosenwald Fund has attempted to capitalize in a wholesale way the well known fact that a small amount of anti-syphilitic treatment will render patients non-infectious. In a few selected areas it attempted mass sterilization of the colored population based upon extensive serological survey. It is too early to judge the effectiveness of this attack.

It is proposed to bring to attention in this paper a more direct, intensive, epidemiological attack upon syphilis and to submit the experience of our office and clinic in the use of this method

during the last 2 years. The nature of this approach is identical to that used in the control of other infectious diseases. It depends upon a simple epidemiologic investigation of every early case of syphilis which comes under observation. This investigation is directed toward ascertaining the identity of the person from whom the patient acquired the disease, and the identity of other persons exposed to the same source or to the patient since infection. Having listed as completely as possible the names and addresses of exposed persons, the next step is to persuade as many as possible to seek immediate medical advice with a view to early diagnosis and treatment if needed. The direct effect is to institute early treatment in the patient's interest and to reduce to a minimum the infectious period of each new case as it arises.

This procedure differs from that used in many other contagious diseases only in that we are dealing with a sex matter. Persistence and tact are necessary, but the patient in the office or clinic may be depended upon to give the necessary information. There is nothing particularly new about this approach but with few notable exceptions, public health officials have disregarded its practicability and effectiveness.

During the 2 years, September 1, 1931–August 31, 1933, 568 patients were admitted. Of these, 193 were questioned regarding sex contacts, the names and addresses of possible sources

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

TABLE I

DISCOVERY OF EXPOSED PERSONS THROUGH QUESTIONING OF ORIGINAL CASE AND ADMISSIONS TO THE CLINIC CONSEQUENT UPON FOLLOW-UP

	Original Cases	Named	Contacts							
			Individuals Represented	Consequent Admissions						
				Voluntary No.	%	Follow-up No.	%	Total No.	%	
White	67	129	101	18	18.0	42	42.0	60	60.0	
Colored	90	216	177	19	10.7	47	26.5	66	37.2	
Total	157	345	278	37	13.3	89	32.1	126	45.3	

of infection and contacts since infection. Questions were limited to the following groups: patients from the city, county and adjoining districts, since we had no means of following up patients in distant localities; patients of all ages having recent infections or in infectious stages; all patients between the ages of 15 and 30 years since these are more apt to have recent infections, and being in the ages of greater promiscuity, are more apt to spread the disease. This selection was arbitrary, each case being judged on its merits. Of the patients questioned, 157 or 81.3 per cent gave the desired information; 34 professed ignorance of the real identity of their consorts or named contacts in distant localities, while 2 refused to name their contacts and facts concerning 1 of these were cleared up by a second patient.

The follow-up of contacts was started immediately upon their identification. Infectious patients were started on sterilizing therapy as soon as possible and all suspects placed under observation, treatment being instituted at the first diagnostic evidence of infection. Each patient was instructed to try to get his or her contacts to be examined. Letters were sent to contacts advising them to report for examination. A

nurse visited contacts and urged them to consult their physicians. When other measures failed, contacts were reported to the health officer.

The discovery of exposed persons through questioning the original cases, and admissions to the clinic consequent to follow-up are shown in Table I. One hundred and fifty-seven patients questioned gave 345 names which, removing duplicates, involved 278 individuals, 126 of whom were admitted to the clinic, 37 coming for examination voluntarily. Undoubtedly some others would have come in eventually, but through follow-up measures we were able to bring in 89 others, many of whom were ignorant of the possibility of infection. Follow-up increased the proportion of infected individuals who were brought under treatment in the early stages, thereby reducing the period of infectiousness and increasing the possibility of cure.

Table II shows the admissions of contacts to the clinic consequent to the various agencies of approach or because of their own volition. The effective methods are varied. There was little compulsion as noted by the fact that the aid of the health officer was solicited in only 7 instances. The later method was used as a last resort in

TABLE II

ADMISSIONS TO THE CLINIC OF INDIVIDUALS NAMED AS CONTACTS BY THE ORIGINAL CASES
CONSEQUENT TO VARIOUS AGENCIES OF APPROACH OR BECAUSE OF THEIR OWN VOLITION

Follow-up Through	Consequent Admissions to Clinic

	25	17	24	23	49	40	89
Voluntary	9	9	7	12	16	21	37

selected cases, all information being kept confidential so far as possible.

The syphilitic seeking advice may be the means of uncovering many other patients just as we may determine carriers of other infectious diseases. Through careful history taking it is possible to trace the transmission from person to person with a fair degree of

accuracy. Such an example is shown in Figure I. Of this group 19 were placed under observation within a 2 month period. We were unable to locate the remainder. No new infections have been traced to any of this group since it was cleared up 20 months ago.

A summary of the entire study is shown in Table III. The original

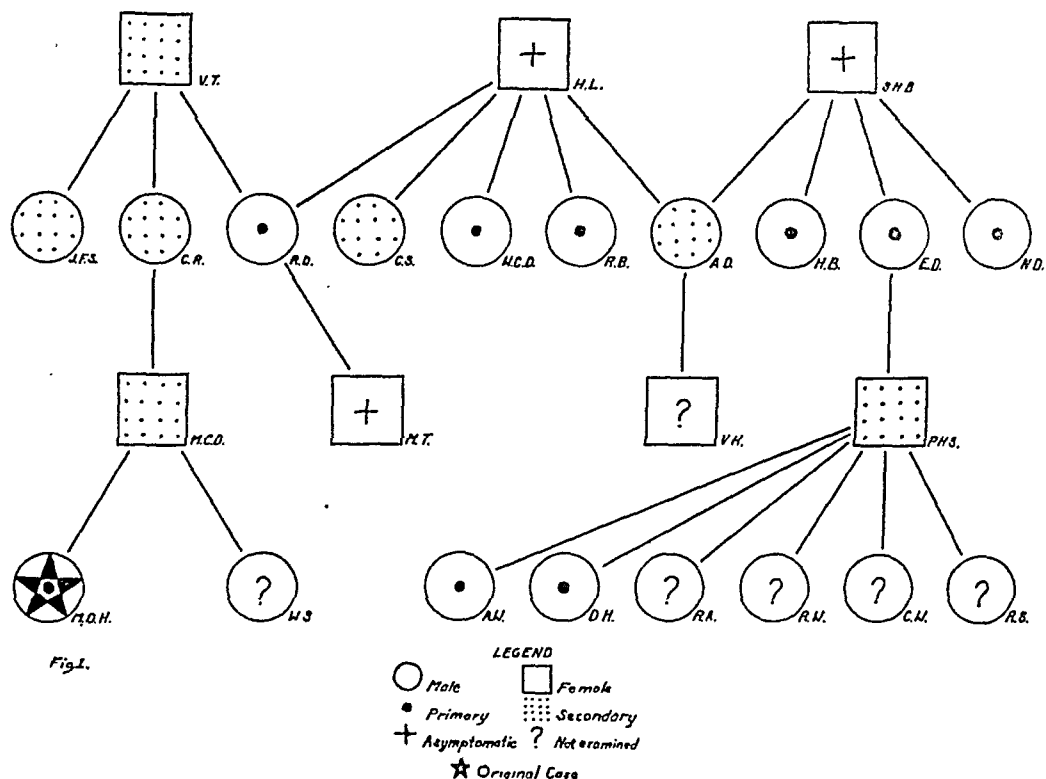

TABLE III

NUMBER OF EXPOSED CONTACTS PER CASE AND ESTIMATED NUMBER OF INFECTED CONTACTS PER CASE OBTAINED BY FOLLOW-UP INVESTIGATION

	Original Cases	Exposed Contacts						
		Total No.	No. per case	Admitted to Clinic			Estimated	
				Total No. (d)	No. Found Infected (e)	Per cent Infected (f)	Total No. Infected* (g)	No. Infected per case (h)
(a)	(b)	(c)	(d)	(e)	(f)	(g)	(h)	
White	67	101	1.50	60	48	80.0	80	1.20

* Estimated Total Number Infected obtained by applying percentage in sample group (d) to total number of exposed contacts (b).

FIGURE I
TRANSMISSION FROM PERSON TO PERSON

cases here embrace all patients who named contacts. Contact exposure rate is shown in column (c). This exposure rate is an index of promiscuity and is not related directly to the spread of syphilis. It is true that a decrease in this rate will necessarily reduce the incidence of the disease. It is toward the reduction of this figure that sex educational measures are directed, but results from any attack at this point will be slow to materialize. The infected contacts per case is shown in column (h). It is this figure in which we are most interested, and diligent contact follow-up will reduce this. So long as this figure remains greater than 1.0 an increase in the incidence of the disease is indicated. When it becomes less than 1.0 a decline is indicated. The immediate follow-up of contacts with resulting sterilization will tend to lower the infected contact rate and this procedure

can be more readily carried out than the elevation of the moral standards. The accuracy of the figures given here is limited by the accuracy and completeness of the information obtained. The estimates may be higher than the actual number of infections since those persons presenting themselves to the clinic probably include a majority of the infected individuals, who had reason to come. For every patient diagnosed or examined there was at least one who was not seen. The incidence is probably lower in the latter group.

A similar study applied to source cases is shown in Table IV. Each patient was shown by analysis of histories to be the source of at least one infection. The white patients of this class present a contact exposure rate much higher than in the general group, whereas there is slight increase in the promiscuity index in the colored source

TABLE IV

NUMBER OF EXPOSED CONTACTS AND ESTIMATED NUMBER OF INFECTED CONTACTS PER CASE KNOWN TO BE THE SOURCE OF AT LEAST ONE INFECTION

	Source Cases	Exposed Contacts						
		Total No.	No. per case	Admitted to Clinic			Estimated	
				Total No. (d)	No. Infected (e)	Per cent Infected (f)	Total No. Infected (g)	No. Infected per case (h)
	(a)	(b)	(c)					
White	24	62	2.5	51	46	90.1	56	2.3
Colored	27	54	2.0	39	36	92.3	50	1.8
Total	51	116	2.2	90	82	91.1	106	2.0

cases. This difference is due in part to the fact that several clandestine prostitutes are represented in the white source cases. In addition we found it more difficult to obtain full information from the colored patients. The infected contact rate is also considerably higher in the white group than in the colored in which commercialized vice is negligible. Through the follow-up of prostitutes a great step is made in preventing the spread of syphilis in the white population. In the colored race the entire population must be dealt with.

A further analysis of the stage of the disease in the source cases reveals that with 1 exception the disease was early, having been acquired within a year. This was a delinquent patient, with little treatment, who developed a mucocutaneous relapse and infected his fiancée through kissing. Of the 51

known source cases, 8 had primary lesions at the time of admission, 22 had secondaries and 20 were diagnosed serologically, but the histories indicated early infections. Efforts should be directed toward treating these patients and rendering them non-infectious.

SUMMARY AND CONCLUSIONS

These results show that it is practical to trace sources of infection and exposures in syphilis. A large majority of new patients will volunteer the necessary information and the follow-up may be readily carried out by the clinician with infrequent aid of law enforcement. Immediate follow-up by means of letters and personal communications is sufficient to increase greatly the proportion of exposed persons brought under treatment in early stages.

Arsenic Poisoning by Pies

CHARLES H. LA WALL, F.A.P.H.A., and JOSEPH W. E. HARRISSON

*Chemists to Bureau of Foods and Chemistry, Pennsylvania Department
of Agriculture, Philadelphia, Pa.*

EARLY in January, 1934, a number of persons in the northeast section of Philadelphia were made sick by eating pies manufactured by a local baker. The pies were of different varieties, including apple, lemon, and mince. The members of the baker's own family were among those who had suffered illness after eating portions of the pies. The symptoms were those of gastrointestinal irritation, all of the cases being characterized by vomiting and diarrhea. Investigation of this situation by John H. Tryon, General Agent of the Bureau of Foods and Chemistry of the Pennsylvania Department of Agriculture, resulted in his bringing to our laboratory a specimen consisting of half a lemon pie.

Analysis of the pie revealed the presence of arsenic in remarkably large amounts. The weight of the sample submitted was 375 gm., of which 255 gm. was filling, and 120 gm. was crust. A quantitative determination of the arsenic in both crust and filling showed 0.184 per cent of arsenic trioxide in the crust and 0.015 per cent of arsenic trioxide in the filling. This pointed clearly to the fact that the contamination was probably due to some ingredient used in the crust. The bakery was visited and a number of samples of raw materials taken for examination, none of which was found to contain arsenic. The baker then recollected that the crust of all of the pies made on the day previous to the one on which the people became ill had been made with corn meal which was part of a lot

purchased at an auction sale a few days previously, which had included the stock of a grocery store which had become bankrupt. He recollected also that one of the cartons of corn meal had been opened and was only partly filled when he received it. Investigation through the auction company and subsequently through the former manager of the store whose products had been sold, revealed the fact that there had been a box of corn meal opened and the contents mixed with sugar and rat poison, then put back and kept for use in poisoning rats. The store manager also admitted that this package of corn meal had not been labeled and that only a few of the people in the store knew about it, and that it could easily have been sold and used as corn meal.

Approximately 150 people were reported as having been made ill from eating 30 pies which the baker admitted having distributed. Many of them required medical attention, but only 1 was taken to a hospital. This patient was discharged within 48 hours as cured. The absence of any fatalities in this case of wholesale poisoning, which was due to gross negligence, may be accounted for by the fact that the arsenic was present in such large amounts, as the calculations showed that each pie contained between 7 and 8 grains of arsenic trioxide. The baker suffered no loss of prestige, apparently, as he and his family had also been victims, and he had been prompt and generous in payment of fees for medical attendance of victims of the accident.

Immunization of Humans with Alum Precipitated Tetanus Toxoid*

D. H. BERGEY, M.D., Dr.P.H., F.A.P.H.A., and S. ETRIS

Department of Research in Biology, The National Drug Co., Philadelphia, Pa.

FOLLOWING a study of the immunizing effect in guinea pigs treated with tetanus toxoid a preliminary report of which has been published¹ our studies were directed to the immunization of humans.

The local effect of the plain toxoid, in causing smarting, lasting for 5 minutes or longer, showed that plain toxoid is an undesirable preparation. An investigation on the effect of the addition of potash alum was carried out. It was believed that the addition of potash alum would enhance the antigenic action of the toxoid, and that by washing the alum precipitate with sterile normal saline solution, following the procedure of Wells, Graham, and Havens² would reduce the content of nonspecific protein in the toxin. The alum precipitated toxoid generally causes neither local nor general reaction, except slight local soreness in persons who are highly susceptible to the proteins in culture media.

The following reports on the antitoxic content of the serums of persons that had received prophylactic injections of tetanus toxoid have been found in the literature:

Ramon and Zoeller³ tested the blood serum of 12 persons that had received 2 or 3 injections of 1 c.c., 1.5 c.c., and 2.0 c.c. of tetanus toxoid. Three or 4

years later the antitoxic content of the serums ranged from 1/500 to 1/6 (American) unit per c.c. of serum.

Another individual received 3 doses of tetanus toxoid and some time later a 4th dose was given; 1 c.c. of this person's serum neutralized 1,500 m.l.d. of tetanus toxin, representing 1.5 units of antitoxin per c.c.

Lincoln and Greenwald⁴ treated 5 adults and 13 children with 3 doses of 0.5, 1.0 and 1.5 c.c. of tetanus toxoid at intervals of a week. Four to 8 months later blood was drawn and the serum tested for antitoxin. The serums of 4 children contained sufficient antitoxin to neutralize 1 to 2 m.l.d. of tetanus toxin, while the serums of the other persons contained only traces of antitoxin. Without further injections of toxoid the amount of antitoxin found in 2 of the children on retesting 18 to 19 months later was sufficient to neutralize 5 m.l.d. of tetanus toxin with 1 c.c. of serum.

Of 7 individuals whose serum contained only a trace of tetanus antitoxin 4 to 8 months after a series of injections of tetanus toxoid, without further injections of toxoid, 6 individuals were retested 12 to 18 months after the first test. Three adults and 1 child still showed only a trace of antitoxin while 2 other children had developed sufficient antitoxin to neutralize 5 m.l.d. of tetanus toxin with 1 c.c. of serum.

Some of the other individuals whose serum contained only a trace of anti-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

toxin 4 to 8 months after receiving three injections of tetanus toxoid were given further injections of 3 or 4 doses of tetanus toxoid. When tested 6 months later 1 c.c. of their serum neutralized from 25 to 75 m.l.d. of tetanus toxin.

Sacquépée⁵ tested the blood of 240 persons that had received a series of 3 injections of tetanus toxoid of 1.0 c.c., 1.5 c.c., and 2.0 c.c. at intervals of 10 days. Six months later he found the following amounts of antitoxin per c.c. of serum: One serum contained $\frac{1}{2}$ a unit (American) of antitoxin, 6 serums contained $\frac{1}{3}$ unit, 120 serums contained $\frac{1}{10}$ unit, 68 serums contained $\frac{1}{30}$ unit, 10 serums contained $\frac{1}{40}$ unit, 22 serums contained $\frac{1}{50}$ unit, 4 serums contained $\frac{1}{60}$ unit, 3 serums contained $\frac{1}{100}$ unit, and 6 serums contained less than $\frac{1}{100}$ unit.

Zoeller and Ramon³ first reported on the use of tetanus toxoid for prophylactic treatment of humans in doses of 1.5, 1.0, and 2.0 c.c. injected subcutaneously.

The toxoid employed in the studies here reported was prepared from a toxin containing 10,000 m.l.d. per c.c. The toxin was detoxified with 0.4 per cent formaldehyde. The toxoid was precipitated with 2 per cent of potash alum, washed twice with and resuspended in normal saline solution. Merthiolate was added to make 1:10,000 dilution. The addition of potash alum to toxoid is believed to retard the rate of absorption and thereby appears to increase the antigenic action, so that it might be used in doses of 1 c.c. The antigenic effect of the alum precipitated tetanus toxoid was tested on guinea pigs by the injection of 1 c.c. The antitoxic content of the blood was tested 6 and 8 weeks later. From the results obtained it is believed that information has been secured as to the prophylactic value of alum precipitated toxoid for the induction of active immunity to tetanus infection in human beings.

Five guinea pigs were given a single injection of 1 c.c. of the alum precipitated tetanus toxoid. Six weeks after the injection of the toxoid the guinea pigs were bled. The serum was separated from the clot and the amount of antitoxin was determined by testing the neutralizing value of the serum when mixed in different amounts with 0.1 L+ dose of standard tetanus toxin and injected subcutaneously into normal guinea pigs.

It was found that a dose of 2.0 c.c. of pooled guinea pig serum, when mixed with 0.1 L+ dose of standard tetanus toxin and injected into the subcutaneous tissue of normal guinea pigs, gave protection to the animals, while 0.2 c.c. of the guinea pig serum failed to protect. Each c.c. of the pooled guinea pig serum, therefore, neutralized at least 50 m.l.d. of tetanus toxin, or contained $\frac{1}{20}$ of a unit of antitoxin per c.c.

Eight weeks after the injection of the dose of tetanus toxoid the guinea pigs were again bled and the pooled serum was tested in the same manner. In this test 0.2 c.c., 0.3 c.c. and 0.4 c.c. each gave complete protection against 0.1 L+ dose of tetanus toxin, representing the neutralization of at least 500 m.l.d. of tetanus toxin or $\frac{1}{2}$ unit of antitoxin per c.c.

Our study of the antigenic effect of a single dose of alum precipitated tetanus toxoid in human beings was started on 33 adults and on a boy 10 years of age. About 5 c.c. of blood was first procured to ascertain whether normal persons have tetanus antitoxin in their blood. None of the specimens of normal blood showed the presence of measurable amounts of antitoxin.

Immediately after withdrawing blood from 34 individuals each received an injection of 1 c.c. of the alum precipitated tetanus toxoid by deep subcutaneous injection into the upper portion of the arm.

The serums of 8 of the 34 persons that had received a dose of 1 c.c. of the alum precipitated tetanus toxoid from 25 to 42 days earlier, were tested for antitoxic content, and 4, who were within the age group of 20 to 30 years, showed from 1/1000 to 3/1000 of a unit of antitoxin per c.c. The other 4 tested showed only traces of antitoxin. The 4 that showed measurable amounts of antitoxin had received the dose of antitoxin only 25 days prior to the tests. The serums of 2 individuals, who were over 50 years of age, when tested 68 days after treatment with tetanus toxoid showed only a trace of antitoxin.

It is realized that more time must elapse before measurable quantities of antitoxin can develop in human beings, especially in persons over 50 years of age. However, since guinea pigs receiving a dose of 1 c.c. of the alum precipitated tetanus toxoid developed as much as $\frac{1}{2}$ of a unit of antitoxin in 1 c.c. of serum in 8 weeks, it is believed that human beings after an injection of a dose of 1 c.c. will show at least 1/250 of a unit of antitoxin in 6 to 8 months.

The relative importance of active immunization with tetanus toxoid over passive immunization with tetanus antitoxin is readily appreciated by those who have been engaged in the control of diphtheria infection. The incidence of diphtheria infection remained relatively high in different communities until active immunization with T-A mixture, and more recently with diphtheria toxoid, became a routine procedure, especially in the protection of children in the preschool age.

It is believed that active immunization against tetanus infection by the use of alum precipitated tetanus toxoid, is of great importance in conserving health, especially for those individuals within certain age groups and for those engaged in civil and military pursuits where the potential danger of tetanus

infection is high. Active immunization against tetanus will materially lower the incidence of tetanus infection in persons engaged in certain industrial occupations: in railroad employees, in miners, in lumbermen, in those engaged in agriculture, and especially in the personnel of the military services. Active immunization against tetanus infection is especially indicated for anyone who is engaged around machinery in industry, or those who ride in automobiles and trucks, in the highly congested traffic on our public highways.

Ramon and Zoeller³ have pointed out that if a person actively immunized against tetanus, should meet with an injury, he should not receive a dose of tetanus antitoxin (as would be the practice with a nonimmune person) but should receive a second dose of toxoid. This second dose would quickly raise his immunity to a higher level and protect him against infection. From the reports in the literature with regard to the persistence of the active immunity it is evident that it would not be necessary to administer a dose of toxoid after each injury. In persons who are injured frequently a dose of toxoid given annually would probably give ample protection.

There is as yet no fixed opinion as to the degree of immunity against tetanus that should be attained from the first dose of tetanus toxoid, the "primary stimulus." French investigators have so far reported no occurrence of tetanus infection in persons actively immunized by a series of 3 injections of plain toxoid.

It is believed that we may take the experience with diphtheria toxoid as an index of the degree of active immunity necessary for protection against tetanus infection. Diphtheria toxoid that induces the development in 6 weeks of 2 units of antitoxin per c.c. of serum in a normal guinea pig, is considered satisfactory for prophylactic use in humans whether 1 or 2 doses are ad-

ministered. It appears reasonable that a tetanus toxoid inducing the development, in 8 weeks, of $\frac{1}{2}$ of a unit of antitoxin per c.c. of serum in a guinea pig of standard weight may also be satisfactory whether 1, 2, or 3 doses are administered. A Schick negative individual has $\frac{1}{30}$ of a unit of diphtheria antitoxin in each c.c. of his blood serum. On this basis it is believed that a person who has been treated with tetanus toxoid should have at least $\frac{1}{250}$ unit of tetanus antitoxin in his blood serum 6 to 8 months later. From the evidence contained in the reports on the antitoxic content of the serum of treated persons (Ramon and Zoeller,³ Sacquépée,⁵) it is evident that the 3 doses injected by the French investigators generally induced even a much higher antitoxic content.

The development of active immunity against tetanus in the treated individuals is influenced by several factors. The age of the individual is a definite factor in the development of immunity to tetanus as well as other diseases. Lincoln and Greenwald⁴ found that 4 of 13 children, 4 months after treatment, had sufficient antitoxin in their blood to neutralize 1 or 2 m.l.d. of tetanus toxin, while 5 adults and 9 other children showed only traces of antitoxin.

In our own studies on the serums of 8 individuals we found that 4 persons between 20 and 30 years of age had developed measurable amounts of antitoxin 25 days after receiving a dose of tetanus toxoid while 2 of the 8 individuals who were over 50 years of age had not developed measurable amounts in 68 days.

The development of tetanus antitoxin in the blood of persons is a slow process and requires several months before appreciable amounts of antitoxin can be detected. Lincoln and Greenwald found that of 6 individuals, 3 adults and 3 children, who, 4 to 8 months after

treatment, showed only a trace of antitoxin, and were not reinjected, 2 of the children, 12 to 18 months later had developed sufficient antitoxin to neutralize 5 m.l.d. of tetanus toxin. From these results it is evident that time is an important factor in the development of tetanus antitoxin in human beings.

Other factors, of unknown nature, also influence the development of antitoxin as shown by the variation in the degree of immunity induced in different horses treated with the same tetanus toxoid; in the treatment of different guinea pigs with the same tetanus toxoid; and the variation in the antitoxic content of the serums of human beings. The factor which is probably of greatest influence in this particular is the physical condition, as influenced by other diseases, of the horse, guinea pig, or man, at the time of receiving the treatment.

Tetanus toxoid should not be used for therapeutic purposes. It should not be injected into a nonimmune person at the time of receiving an injury. Persons actively immunized with tetanus toxoid when injured, should receive another dose of tetanus toxoid, while persons who are not actively immunized should receive a dose of tetanus antitoxin. In such an individual active immunization may be carried out by giving a dose of tetanus toxoid about 2 weeks after the receipt of a dose of tetanus antitoxin, following an injury.

The points of special importance in the use of alum precipitated tetanus toxoid are: (1) The induction of an active immunity in 3 to 6 months. (2) The absence of either local or general reaction from the dose of alum toxoid, except slight local reaction in occasional individuals who are highly sensitive to the proteins contained in culture media. (3) Absence of danger of sensitizing the individual to horse serum proteins such as may occur from repeated prophylactic doses of tetanus

antitoxin when used for prophylaxis following injuries.

Houston Adopts a Cross-Connection Idea Worthy of Note

H. N. OLD

Sanitary Engineer, U. S. Public Health Service, New Orleans, La.

THE officials of the City Water Department at Houston, Tex., are "on their toes" and apparently taking advantage of every opportunity to safeguard the quality of the municipal water supply. As an evidence of this alertness there is shown below a rather commendable policy which has been adopted in the furtherance of their campaign seeking the elimination of all cross-connections.

The writer was afforded the privilege recently while in Houston of reviewing the reports of a survey and resurvey of a condition in the basement of a large office building at which several connections between the city water supply and the building sewer were found to exist. Unfortunately the attitude of the building management was distinctly antagonistic toward making the required changes, expressing itself as believing that the matter was of no importance and simply an attempt on the part of the City to "give somebody a job."

The discussion of the Chicago amebic dysentery outbreak as presented in *Time* of February 12, 1934, was pasted upon the left hand side of a City of Houston letterhead and numerous photostats produced, one of which was used in

replying to the officials of the office building referred to.

In the course of a sanitary survey of the Houston water supply in 1928 some 6 or 8 instances of cross-connections between the municipal and private supplies were recorded with the expectation that this list would probably be increased to 15 or 20 by a comprehensive cross-connection survey.

On March 4, 1930, a cross-connection ordinance was passed by the city and on December 15, 1930, one engineer was assigned exclusively to cross-connection surveys and elimination. During the 3 year period, 1931 to 1933 inclusive, there were made 199 surveys (including resurveys) and 113 cross-connections definitely eliminated, 44 in 1931, 44 in 1932, and 25 in 1933.

The city ordinance includes authority for the discontinuance of water service until such time as conditions are made safe in addition to a maximum fine of \$200 each day after the period granted for correction constituting a separate offense.

It is believed that the success of this phase of the water supply sanitation program at Houston has been due to the efficiency with which the surveys

have been conducted, the diplomacy on the part of the water department officials in negotiating with building owners involved and the distinctly coöperative attitude on the part of the large majority of these property owners.

LETTER SENT OUT BY HOUSTON WATER DEPARTMENT

God & Plumbing

Like typhoid, the germs of amebic dysentery may be spread through water contaminated by sewage. But when Chicago belatedly reported a full-fledged dysentery epidemic as *A Century of Progress* was closing wiseacres assumed that the second city in the land had up-to-date sanitation and therefore the germs could have been transmitted only on food infected by dirty-handed hotel employees (*TIME*, Nov. 20). Last week in the *Journal* of the American Medical Association a committee of experts on sanitation and tropical diseases, including National Institute of Health Director George W. McCoy, Mayo Clinic's Dr. Thomas B. Magath & Maryland's Board of Health Engineer Abel Wolman, reported its recent investigations in Chicago. The experts laid blame for the epidemic on an Act of God and defective plumbing in the two hotels which were the chief sources of infection. The committee clemently referred to the hotels as C and A, but everyone knew it meant South Michigan Boulevard's big, popular Congress and its smaller neighbor, the Auditorium.

The committee found the hotels' water and sewerage piping systems so old and faulty that when heavily taxed they would let waste from bathtubs and toilets siphon back into drinking water pipes. Water and sewer pipes were cross-connected. Sewers were leaky. Last June 29 a heavy rain overloaded sewers near the Auditorium, flooded its basement. Three days later another cloudburst broke two of the Congress' sewers, filled its ice storage house and covered its food-packed basement three to six inches deep with muck.

Connections between sewage and water pipes have since been cut. But, said the committee: "Unless the antiquated plumbing and conditions of food-handling found in Hotels C and A are remedied, there seems to be no warrant that a recurrence of the outbreak here considered may not develop under similar conditions."

Up to last fortnight 41 deaths and 721 cases of amebic dysentery in 206 cities had been apparently traced to Chicago. The committee cleared Chicago's Health Commissioner Herman Niels Bundesen of laxness or negligence in handling and publicizing the epidemic. Last week Commissioner Bundesen promised rigid plumbing and food inspection, called for an emergency staff of 20 sanitary engineers.

TIME, February 12, 1934

February 28, 1934.

Blank Bank and Office Bldg.,
Houston, Texas.

Att'n Mr. John Doe,
Vice-President

Gentlemen:

Referring to our letter of the fifth of February and your answer dated February 8th, concerning the existing cross-connections between water service lines and sewer lines in the basement of your building, we are informed that no steps have been taken to eliminate these cross-connections as requested by us.

This office made its first survey of your piping connections in July, 1929, and the condition complained of was in existence at that time. Due to some oversight, the matter was not brought to the attention of the former owners of the building. A re-survey was made on the thirtieth of January, this year, in connection with our usual routine and the cross-connection was found to still exist.

In March, 1930, the City Council approved an ordinance covering cross-connections, a copy of which is attached hereto, and this office has been working since that time on the elimination of these health hazards. Your attention is invited to the article reprinted on this page as evidence of what might occur if such conditions as now exist in your piping were allowed to continue.

In accordance with the provisions of the above mentioned City Ordinance, you are hereby notified that the cross-connection between city water lines and the sewer, now existing in your building, must be eliminated within the time specified in said City Ordinance or we shall be forced to take such steps as will protect the purity of our public water supply.

We believe that with these facts at hand we may expect your complete coöperation toward the end that the health of your employees, tenants and the public may not be subjected to the hazards that now exist.

Yours very truly,
J. B. Dannenbaum, Engineer,
Water Division

Diphtheria Prevention in Charleston, West Virginia

HUGH B. ROBINS, M.D.

Health Commissioner, Charleston, W. Va.

IN 1929 a campaign of diphtheria prevention was organized jointly by the City Health Department and the School Health Service. Toxoid was offered to all children in the first 6 grades. The response was very gratifying, it being estimated that over 75 per cent of these children were protected.

During the following 3 years the work was restricted to students entering the Charleston schools for the first time. For several reasons the immunization program was not pushed and the per cent of children immunized decreased. During these years there was very little change in the case and death rates from diphtheria. The Health Commissioner realized that the system which was followed was inadequate and reached only a small per cent of the preschool children. These campaigns, however, stimulated an interest in diphtheria protection on the part of the physicians of the city. There was not only an increase in the interest on the part of the physicians but a growing hostility toward the official health agencies providing the services which the physicians felt belonged to them.

In May, 1933, a paper was presented at the Annual Meeting of the West Virginia Medical Association in Charleston, outlining the program of professional participation which has been sponsored in Detroit by the Wayne County Medical Society and the Department of Health, and in three rural counties of southwestern Michigan by

the W. K. Kellogg Foundation. So great was the response to this paper that an informal luncheon meeting was entirely devoted to further discussion of this subject. The officers of the Kanawha County Medical Society and the Health Commissioner of the City of Charleston decided that the next diphtheria campaign should be along the lines of the programs established in Michigan.

When the public schools opened in September, such a plan was earnestly considered but the financial condition of the City of Charleston prevented the Health Department from initiating the program at that time. The Health Commissioner had decided that it would be necessary to have toxoid available without cost to the physicians if the campaign were to be a success. During the month of September, 8 cases of diphtheria were reported and in the first 8 days of October, there were 5 additional cases. While attending the Annual Meeting of the American Public Health Association at Indianapolis, the Health Commissioner decided that the diphtheria campaign was an urgent need in Charleston. The State Health Commissioner offered to furnish toxoid without charge to physicians. Returning to Charleston, the Health Commissioner met with the local society and it was decided that immediate action should be taken. The President of the Medical Society appointed a Public Health Committee consisting of 5 members, 2 of whom

pediatricians. During the month of October there were reported 21 cases of diphtheria and the disease seemed to be on the increase. Reports from the State Health Department indicated a rapid increase throughout southern West Virginia.

The Commissioner decided that 2 weeks would be required to prepare both the physicians and the public. An outline was sent to all physicians explaining the nature of the proposed campaign and requesting each physician to return a card indicating whether or not he would be willing to coöperate in the project. There are about 125 physicians in active practice in Charleston and, of this number, 88 agreed to coöperate. The committee divided these 88 names into 5 groups and each member of the committee agreed to telephone or personally see the physicians on his list and thoroughly inform them of the details of the plan.

The plan briefly was as follows: (1) On November 9 and 11, at the hours from 3:00 to 5:00, all coöperating physicians would be in their offices, prepared to immunize children; (2) for those whom the physician judged able to pay, a charge of \$1.00 per visit would be made; (3) those unable to pay would be immunized without charge; (4) individuals desiring to come to the physician at other hours than those specially designated would be charged whatever the physician deemed proper; (5) there would be no free clinics or school clinics held by the Health Department nor by the School Health Service. A mass meeting was held for the detailed instruction of the coöperating physicians.

During the 2 week period immediately preceding the opening of the campaign a constant program of public instruction was carried on through the press. The local radio station offered its facilities for evening talks and 3 radio talks were given. Hundreds of

pamphlets urging immunization were distributed to the school children in the lower grades. The public health nurses urged immunization wherever and whenever they made calls for any purpose. A series of talks to all the Parent-Teacher Associations was inaugurated.

Cards were obtained and distributed to physicians for the purpose of recording the name, address, age, date of doses (2 dose toxoid being used), and a space was provided for recording whether the patient paid or was considered a charity case. At the same time pads of immunization certificates were left with the physician to give to the parents upon completion of immunization.

During this time new cases of diphtheria were being reported almost daily, and 2 deaths occurred. The public was kept fully informed concerning the prevalence of the disease. In accordance with the pre-determined plan the physicians devoted a total of 4 hours of their time to the immunization program on November 9 and 11. Two days later, that is, on November 13, the Health Department called upon all the coöperating physicians to report the number of children who had received a first dose of toxoid. The tabulation showed that approximately 1,200 children from 6 months to 6 years of age, and another 1,200 over 6 years of age had received their first treatment. This represents approximately two whole age groups in Charleston. The high per cent of pre-school children protected was especially impressive. Postcards were supplied to all physicians to be sent to parents just before the second dose of toxoid was due.

In the middle of December report cards were collected from all coöperating physicians, and a second letter was sent to the parents of those children who had not returned for their second dose of toxoid. A tabulation made at that time showed a total of 2,905 com-

plete immunizations and 1,404 of these were for children from 6 months to 6 years of age. For individual years there were as follows: 6-12 months, 162; 1-2 years, 212; 2-3 years, 245; 3-4 years, 286; 4-5 years, 250; 5-6 years, 249; 6-7 years, 222; 7-8 years, 239; 8-9 years, 210; 9-10 years, 182; 10-11 years, 181; 11-12 years, 114; 12 and over, 303; and miscellaneous 50. The miscellaneous represent the group in which no age was recorded. It is estimated that there are 5,500 children in Charleston between 6 months and 6 years of age. It would therefore appear that about 25 per cent of these children were immunized during the campaign.

In order to make a further check on this figure, the school physician sent questionnaires to the parents of all first grade children in 5 representative schools, 4 white and 1 colored. In the questionnaires it was asked how many children were in the family under 6 years of age; of these how many had been immunized before the campaign and how many were protected during the campaign. The same question was asked for children from 6 to 12 years of age. The questionnaires were satisfactorily returned and the figures indicated that approximately 50 per cent of both groups are now immunized and that these are rather evenly divided into 25 per cent protected during the campaign and 25 per cent protected prior

to the campaign. The closeness with which this survey approximates the actual figures reported by the physicians leads us to believe that the estimate is a very fair one.

During the month of January, 1934, there were reported 7 cases of diphtheria. In February no case was reported. During the first week of March there was reported 1 case, that of a woman 37 years old. A special report received from 24 of the coöperating physicians indicated that the parent had paid for the service in 462 instances, while 459 services were given without charge. It therefore appears that the parents paid for the service in 50 per cent of the cases.

It has been shown that an immunization campaign can be successfully carried on without the aid of mass clinics by the official health agency. Active coöperation on the part of the local physicians under the direction of a strong steering committee is essential to success. The campaign played a definite part in checking an epidemic of diphtheria. No reactions of serious import were reported. If the 1 dose alum toxoid had been used, approximately 175 more immunizations could have been counted. The Kanawha County Medical Society has gone on record favoring a continuation of this type of medical participation in public health work and its extension to other immunizations as soon as practicable.

ice, while in 1930 the number had reached 31. Twenty states had specifically allotted funds to laboratory service in 1915, and the number increased to 42 in 1930 with several others maintaining laboratory work through unallotted appropriations. Some 16 states appear to have had sanitary engineering service organized in 1915, but in 1930 all states had service of this character organized either under a special division or in relation to another departmental activity. Thus, in 3 of the basic functions of a state health organization, steady growth over a period of 15 years has resulted in nationwide development of emphasis on the technical excellence of service as measured by the organization of technical divisions.

Another fact indicating this same trend is the increasing emphasis on special training of public health personnel. Within the period under discussion a number of university courses and no less than 3 schools of hygiene and public health have been developed as facilities for graduate training of personnel entering the public health field; and it is becoming the exception rather than the rule to find untrained individuals directing technical functions in our state health departments. Perhaps this is, of all factors, the most important, for, though statistical interpretation of its value is not possible, the investment is in intellectual values which, obviously, determine all trends.

Another evidence of the movement toward an increasing specificity of objectives is the tendency toward definite planning of programs in both their major and minor strategy and toward subsequent analysis of results. In other words, there seems to be a tendency to the adoption of a controlled experimental approach with objective appraisal of results for the purpose of increasing the specificity and effectiveness of methods. In connection with

this trend, there has developed not only the method of appraisal in local health activity but deliberately planned experimentation in methods for the application of existing knowledge has been executed on a scale not hitherto attempted.

In the light of these facts as evidence of an increasingly excellent professional and technical approach to state departmental administration, is there any doubt that our practice will become increasingly effective?

Reference has been made to the interrelationship and interdependence of the health organizations of the several elements of government. A third encouraging trend to better health service for the country as a whole is indicated by the evidence of increasing interest on the part of state health departments in local health departments, especially in rural health organizations which constitutes the weakest link in our chain of facilities for public protection. Less than 600 of our counties are protected by health departments organized on a whole-time basis yet even this is an improvement over the situation in 1926 at which time only 307 counties were so organized. This progress is unimpressive if it is attained in spite of difficulties and discouragement which at times may be met. The interest of the state is shown by the increasing expenditures from their budgets to the maintenance of rural health organizations, and this sum amounts to nearly 15 per cent of the total of some 501 health departments. In the foregoing discussion I have cited 3 trends which indicate the general health organization which with single seem to be pursuing

FIGURE II

skeletal muscle (Figure 1b), brain (Figure II,f) and spleen and lungs. The striking thing is that in spite of this widespread manifestation of infectivity of this organism the liver rarely showed lesions. This organ appears to be

highly resistant to infection although the gall bladder often was the site of abscesses (Figure II,d) and the bile nearly always contained abundant yeast-like cells and much long mycelium (Figure II,e).

The intensity of the reaction was revealed more clearly in the kidneys and lungs. The kidneys were 2 to 2½ times normal size, the capsule was tense and the surface appeared greyish white and granular, due to numerous pinhead to pinpoint size abscesses (Figure I,a). The cut surface showed the cortex to be markedly thickened and whitish in appearance due to numerous small abscesses. The medulla was deeply congested and contained only a few small abscesses (Figure I,b).

The lungs were characterized by numerous sub-pleural petechial hemorrhages (Figure I,c). The cut surface also showed some small hemorrhagic spots and thrombosis of the large vessels was occasionally seen; 8 per cent of these animals died of pulmonary thrombosis.

The lesions produced by *M. candida* were so much fewer and less intense in reaction that after a few post-mortems we could distinguish the species of organism with which the animal had been inoculated without consulting our notes.

The lungs revealed in the case of the *M. candida* animals relatively few sub-pleural hemorrhages (Figure I,c) and the kidneys showed no increase in size; the surface contained only an occasional small abscess (Figure I,a). The cut surface revealed a cortex which was not thickened and contained only an occasional small wedge-shaped grey-

ish-white area which extended through the medulla (Figure I,e). The medulla contained a few greyish-white areas but did not appear congested. No other tissues or organs contained lesions.

From this description of the gross pathology one cannot escape the strong suggestion that the process is primarily thrombotic, but that it is purely thrombotic does not seem likely. For instance, why do the arterioles of the glomeruli of the kidney collect the fungus cells in the case of *M. albicans* and not those of *M. parapsilosis* or *M. candida*? Why does *M. albicans* produce lesions in the arterioles of the skeletal muscles and the other 2 do not? Why do the capillaries of the liver escape the plugging effect of even *albicans*? These questions we undertook to answer by a determination of the relative size of the cells of organisms of the 3 groups, and by a determination of the growth capacity of the 3 species within the animal body. The result of determination of the size of the cells is shown in Table II.

It is apparent that there is not sufficient variation in the size of the cells to explain the difference in the species virulence. While it is true that *M. parapsilosis* has cells which average slightly smaller than either *albicans* or *candida*, still *candida* has an average cell size larger than *albicans*. It is apparent, therefore, that the difference in the size of the cells does not offer

TABLE II

an explanation for the difference in infectivity of the organism and that the process cannot be entirely thrombotic.

To investigate still further the significance of the size of the cells in the pathology of the experimental disease we next made up suspensions of the different species in normal salt solution and killed them with formaldehyde. When they were proven to be dead by culture the cells were again measured and intravenous injections done. This experiment resulted in no illness in any animal and post-mortem examinations revealed no gross lesions. The microscopic examination of these tissues revealed no reactions of even a mild type.

At this point we felt certain that simple thrombosis as an explanation of our post-mortem findings had been ruled out but so far we had no positive explanations to account for the pathology. We now undertook to determine the growth capacity of 3 species in the animal body. We expected that we might be able to accomplish this demonstration by making blood cultures and urine and bile cultures of animals killed at intervals varying from 2 hours following the injection up to 6 days. We expected that if one species showed a greater capacity for reproduction in the blood stream than another, the organism showing the least capacity would disappear from the blood stream first, that urine and bile cultures would show fewer positive results and, further, that Gram stain of the microscopic sections of the tissues would reveal in the case of the most vigorous reproducers more abundant mycelium. Table III illustrates the results.

It is apparent from this table that *M. parapsilosis* died very shortly after introduction into the blood stream; that *M. albicans* remained in the blood stream as viable organisms for a comparatively long time and showed evidence of being able to invade tissue by its appearance in both the urine and bile. The milder property of *M. candida* in these particulars is indicated by the much lessened frequency with which it appeared in the urine and bile and its inability to maintain itself for as long a period in the blood stream. This difference was still further substantiated by the examination of tissue removed at varying intervals following injection. *M. parapsilosis* showed, shortly after inoculation, signs of degeneration by the appearance of Gram-positive bodies in the tissue which were beginning to break up and it was never possible in these tissues to demonstrate either budding forms or mycelium. *M. albicans*, on the other hand, demonstrated vigorous powers of reproduction in the capillaries by the appearance in sections of tissue removed at 2 and 4 hours of many budding forms of Gram-positive fungi and frequent strands of mycelium, and as the disease progressed mycelium became more abundant. (Figure II, b and c.) *M. candida* showed Gram-positive yeast-like cells some of which were budding but it never produced mycelium.

Our next experiments were designed to test the evidence obtained that *M. albicans* alone of these organisms was able to invade tissue. Animals were injected subcutaneously, intra-muscularly, intra-pleurally, and into the nasal

750	American Type Culture	M. tropicalis Castellani; Aldo Castellani, Tulane Univ., isolated 1909.

accessory sinuses with standard doses, already described, of *M. albicans* and *M. candida*. *M. parapsilosis* was not used in these experiments since it had been shown that even in large intravenous doses it had no pathogenicity.

The subcutaneous inoculations of *M. albicans* cultures resulted in abscesses which healed in 10 to 12 weeks. The injections into muscle, pleura, and nasal sinuses resulted in septicemia and multiple lesions throughout the body, particularly the kidneys.

M. candida cultures produced by these methods of injection neither local nor general reactions.

The cultures used in these experiments are described in Table IV.

We selected these cultures because of their association with certain clinical manifestations in human cases and because some of them are well known in the literature. The classification as *M. parapsilosis*, *M. albicans* and *M. candida* is our own and was arrived at by methods previously described. As already indicated under the discussion of dosage arrived at by cell counts in a hemocytometer, individual cultures of *M. albicans* vary somewhat in virulence but never so much as to be at all confusing with the other species of lower virulence, *M. candida* or with *M. parapsilosis*, which showed no pathogenicity for rabbits. We made no attempt to step up virulence by animal passage before using the culture in an experiment. It is apparent that some of these cultures have been cultivated on artificial media for many years; i.e., culture No. 4135, American Type Culture Collection, *M. pseudo-tropicalis* Castellani, was one of the most virulent cultures we used; killing in smaller doses and causing more widespread lesions when

inoculated locally into various tissues. Our own cultures had been on artificial media for 5 or 6 years without animal passage.

SUMMARY

In our experience, and from what we can get from the literature, *M. albicans* appears to be the organism most frequently associated with human cases of moniliasis. Many organisms described as different species of monilia have in our hands proved to be cultures of *M. albicans*. The animal experiments reported in this paper demonstrate that organisms belonging to the species of which *M. albicans* is typical are the only ones which can multiply vigorously in the animal body and invade tissue. Although the organisms of which *M. candida* is typical have shown some feeble power of reproduction in the animal body they have demonstrated a very low degree of virulence, and this no doubt accounts for the frequency of *M. albicans* in the case reports found in the literature. Organisms of the *M. parapsilosis* species have shown no pathogenicity for rabbits.

Vitamin G Deficiency*

PAUL L. DAY, PH.D.

*Professor of Physiological Chemistry, School of Medicine, University of Arkansas,
Little Rock, Ark.*

GOLDBERGER and Lillie¹ were the first investigators to describe the pathological condition in the rat due to a deficiency of what is now termed vitamin G (B₂). They observed the following symptoms as characteristic of a deficiency of the newly discovered vitamin, then only recently differentiated from vitamin B: arrest of growth, sticking together of the eyelids with an accumulation of dried secretion on the lid margins, and loss of hair from various parts of the body which sometimes resulted in nearly complete denudation. Some of the animals later developed a dermatitis on one or more of the following sites: ears, neck, chest, legs, or paws. Some animals showed a linear fissuring or ulceration of the angles of the mouth and a lesion on the tip of the tongue.

Other laboratories^{2, 3, 4, 5, 6} soon confirmed the general findings reported by Goldberger and Lillie.

Several years ago, we observed that, in addition to the symptoms previously reported, young rats given a vitamin G deficient diet developed a whitish appearance of the eyeball in a large percentage of cases. Examination with the ophthalmoscope revealed the presence of keratitis (opacities in the cornea) and cataract, and histological sections of such eyes confirmed the diagnosis.⁷ Using our dietary regimen, two other

laboratories^{8, 9} have obtained similar results. In order to determine whether this new deficiency manifestation was peculiar to the rat or general for all species, we extended our experiments to mice¹⁰ and chicks¹¹ and have found cataract resulting from vitamin withdrawal. We are now obtaining similar results with monkeys.

Cataract is any opacity of the lens of the eye or of the lens capsule. In order to make subsequent discussion clear I give briefly the anatomy and pathology of the lens. It is a biconvex transparent body, the function of which is to focus the image of objects upon the retina. The capsule is a homogeneous transparent membrane which covers the entire surface. The lens proper is built up of long, transparent, ribbon-like or prismatic bodies known as lens fibers. Each lens fiber is disposed along a meridian of the lens, and extends from its anterior to its posterior hemisphere. In addition, the lens contains a layer of cells over its anterior surface and just under the capsule—the lens epithelium. These are the only cells capable of regeneration. Their function is to lay down successive layers of lens fibers during growth. Mechanical injury, certain diseases, and some toxic materials cause opacities. The lens is non-vascular, and obtains nutriment by diffusion from the aqueous humor, which lies anteriorly, and is in direct contact with the lens capsule.

Aside from inflammatory changes that may occur only when the capsule is broken, the pathological changes pos-

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

sible within the lens are extremely limited. Friedenwald¹² classifies these as follows:

1. Sclerosis of the lens fibers, which in extreme cases causes impairment of vision.
2. Autolysis of lens fibers, characterized at first by shrinkage of the fibers with the formation of fluid filled clefts, and later by swelling and digestion of fibers, with the formation of amorphous or crystalline precipitates, which, together with fragments of unaltered lens fibers suspended in a fluid of high protein content transmit light very poorly.
3. Proliferation of the anterior lens epithelium, which sometimes forms a dense membrane many cells deep.

The cataracts we have found resulting from vitamin G withdrawal have been characterized in histological section by the two latter changes, that is, autolysis of lens fibers, and proliferation of the lens epithelium (Figure I).

These nutritional cataracts have been prevented by yeast, autoclaved yeast, liver, kidney, and other meats, milk powder, and a wide variety of other foods containing vitamin G. In fact, wherever definite growth has been obtained in a vitamin G assay, cataract

has failed to appear. Wherever rats have failed to grow in a vitamin assay, as in negative controls or in animals which received foods deficient in vitamin G, cataract has developed. It appears, therefore, that for our strain of rats, stock diet, method of care, and deficient diet, the growth promoting vitamin that we are dealing with is the same as the cataract preventive vitamin.

The feeding of a vitamin rich diet to animals which have developed the disease results in a gradual clearing up of all the general and ocular manifestations except the cataract. The opacities in the cornea tend gradually to disappear. New hair appears on the eyelids, the animal in general puts on a new coat of hair, and develops an apparently normal health and vigor. The lens opacities do not disappear, however, as there is no mechanism for the repair of damaged lens fibers (Figure III).

Numerous investigators have observed an ophthalmia as one of the characteristic signs of vitamin G deficiency in the rat.^{1, 2, 3, 4, 5, 6} Of all these investi-

FIGURE I.—Microphotographs of sections of normal and cataractous lenses of Norway rats.

FIGURE II—Photograph of a Norway rat showing cataract resulting from vitamin G deficiency.

gators, Salmon, Hays, and Guerrant³ alone mentioned an opacity of the eyeball. They believed, however, that the opacity centered in the vitreous humor but sometimes invaded the lens.

The question arises: why, if cataract is such a constant accompaniment of vitamin G deficiency, has it not been observed more generally? There are probably several reasons. Even under the most favorable conditions for the appearance of lens changes, *gross* cataract frequently does not appear until after the 70th day. Consequently, if the animals were kept for an 8 or 10 week period only, the cataract might easily be overlooked. Before the gross manifestations of cataract appear, there is frequently a sticky exudate which seals the lids, and only by forcing them open does the cataract appear, so it might easily go unnoticed unless one were looking especially for it. It is also quite possible that in other laboratories, because of different nutritional history, different vitamin deficient diets, and with other methods of care, rats do not develop cataract on G-deficient diet.

As we have been using cataract as a

criterion of vitamin G deficiency in our negative controls, we have naturally chosen those conditions of diet, age and size of animals, size of litters, etc., which would produce cataract with the most regularity and at the earliest age. Therefore, it is not surprising that we have found and reported cataract in a higher percentage of cases than have other laboratories. It is possible that with our experimental regimen we are dealing with one deficiency, and laboratories that have not observed cataract are dealing with a deficiency of some other vitamin.

Are these experimental cataracts due to lack of vitamin G, or some other vitamin? This may depend upon the definition of vitamin G accepted. The cataract preventive vitamin is stable to autoclaving, is soluble in water and dilute alcohol, and insoluble in strong alcohol. The cataract results from a deficiency of vitamin G then, if vitamin G is defined as the relatively heat-stable water—and dilute alcohol-soluble vitamin or vitamins. To those who limit the use of "G" to denote the dermatitis preventive factor, cataract may or may not be due to vitamin G deficiency. Superficially considered, it might seem improbable that the dermatitis preventive factor and cataract preventive factor could be identical. On more careful consideration, however, it seems not only possible but quite probable. The lens is derived embryologically as an invagination of the body-wall ectoderm, and thus is derived from the same germ layer as the skin. Friedenwald says: "The structures most nearly related to it are the hair and the nails."¹² It is therefore not unreasonable to suppose that a deficiency which results in changes in the skin might also produce pathological changes in the lens. It seems that vitamin G deficiency affects chiefly tissues of ectodermal (body-wall) origin: skin,

lining of the mouth, conjunctiva, cornea, and lens.

Although it appears quite probable that both dermatitis and cataract are due to the same deficiency, there is the possibility that cataract and the other ocular changes result from a deprivation of one of the newer and less well known vitamins, of which there appear to be several. Harris,¹³ in 1931, listed 17 new factors of the vitamin B group reported up to that time, and several similar reports have appeared since.

It would appear that, in working with the multiplicity of factors in the vitamin B complex, investigators have given more attention to evidence based upon growth than to that based upon pathological manifestations. Growth can be accurately measured, averaged, and the results statistically analyzed, while it is difficult to give a quantitative statement of the degree of pathological change, such as the extent of dermatitis. For this and other reasons, much of the evidence for the existence of the many new vitamins is based upon growth alone. Chick and Copping¹⁴ recognized this in 1930:

Much difficulty and uncertainty in this field of work is due to the fact that, except in work on the antineuritic vitamin B₁ and to some extent in that on the antidermatitis vitamin B₂, the criterion for presence or absence of these various B vitamins has been the growth (increase in weight) of a rat or pigeon. . . . Advance in this field of work would be much helped if the physiological rôle of the various members of the group were elucidated and the pathological condition following deprivation recognized.

For this reason alone I feel that the cataract which results from a deficiency of a relatively heat-stable vitamin deserves the attention of workers in this field. If cataract results from a deficiency of one of the new vitamins, it is a definite and unmistakable sign to be looked for as evidence of such deficiency. If cataract and keratitis result from the same deficiency as dermatitis, we have another and perhaps better criterion of the deficiency. In fact, dermatitis would seem to be an unsatisfactory evidence of vitamin G deficiency, since Sherman and Sandels⁵ found that it occurred more frequently when there was a small amount of vitamin G present in the diet.

Courtesy of the American Journal of Ophthalmology

FIGURE III. Photograph of an albino rat showing cataract in the left eye as a result of vitamin G deficiency. In this case cataract developed in the left eye first, after which time vitamin G was added to the diet, preventing the development of cataract in the right eye.

In a large series of animals which we have recently followed by weekly ophthalmoscopic examinations,¹¹ keratitis and cataract were the *first* pathological signs observed, excepting alopecia. In some cases cataract preceded the loss of hair. It is quite probable that there were changes in the skin coincident with the changes in the cornea and lens, but due to the structure of the skin, pathological manifestations are not readily evident until far advanced. On the other hand, the lens is a transparent tissue in which very early changes can be seen with the ophthalmoscope without injury to the animal, and with which the daily or weekly progress of the disease can be followed closely.

In order to make pathological records of skin changes comparable to those we keep on rats' eyes, it would be necessary to kill representative animals at weekly intervals, fix and section portions of the skin, and examine with a microscope. In proposing the ophthalmoscope as a new tool for the vitamin biochemist we are suggesting a technique that is simple and rapid.

Good ophthalmoscopes, entirely satisfactory for animal work, are obtainable at less than half the price of an ordinary microscope. A few weeks' experience will enable the research worker to distinguish the various stages in the pathology of the cornea and lens of experimental rats on vitamin G deficient diet.

What is the application of these experimental findings to human cataract? We are becoming increasingly confident that cataract may be expected wherever there is an inadequate intake of vitamin G. All animals with which we have experimented, from chicks to monkeys, have developed cataract as a result of such a deficiency. If man does not, he would appear to be the exception. As the human requirement for vitamin G is not known, it is impossible to state

whether any given human dietaries are deficient enough in this factor to produce cataract.

Clinical cataract results from a number of causes. Two types—congenital and so-called senile—are of obscure etiology. It would seem possible that at least some of these so-called senile cataracts might be the result of vitamin G deprivation. The general appearance of the rat given a subnormal amount of vitamin G, Sherman¹⁵ describes as a picture of "premature senility." He says: ". . . so a liberal intake of vitamin G contributes to a better than average nutritional condition and thus to what McCollum and Simmonds have aptly termed 'the preservation of the characteristics of youth.'" Sherman and Smith¹⁶ state: "The significant improvement in longevity found by Sherman and Campbell resulting from improving a diet already adequate . . . is probably due in part to the higher content of vitamin G. . . ." With such observations upon the picture of premature old age resulting from vitamin G deficiency, and the preservation of youth and increased length of life resulting from a liberal intake of vitamin G, it is possible to make out a plausible case for a possible relationship between vitamin G deficiency and senile cataract. Friedenwald says: "(senile) cataracts may, then, be related to the falling out and blanching of the hairs and to other similar senile changes in epidermal organs."¹² In the light of this statement it seems more than a coincidence that, in our experimental animals, we find a falling of hair and early cataractous changes occurring almost simultaneously.

A discussion of cataract and vitamin G deficiency would not be complete without mentioning pellagra. Cataract does not appear to be any more prevalent among pellagrins than among non-pellagrins of the same age, occupation,

and social class. If experimental cataract is the result of a deficiency of the dermatitis preventive vitamin *per se*, this would argue against the identity of the pellagra preventive and the rat dermatitis preventive factors. It is possible, of course, that pellagra and cataract both result from the same deficiency under slightly different conditions. It may be that pellagra results from a partial deficiency, while cataract results from a more complete deprivation of the same vitamin. A somewhat analogous condition is met with in our experimental animals; diets free enough of vitamin G to produce cataract do not cause the ulcerative type of dermatitis. Under these conditions alopecia is about the only consistent evidence of dermatitis. With less complete freedom from vitamin G, distinct scabby ulcers appear on the skin, but the development of cataract is greatly delayed (Cf. Sherman and Sandels⁵).

In discussing the bearing of the cataract of vitamin G deficiency upon the etiology of pellagra, it is premature to do more than suggest possibilities. Although cataract as a symptom of G-avitaminosis seems to add one more unanswered question to the pellagra problem, it is hoped that it will ultimately aid in the elucidation of this important question.

Although vitamin G withdrawal does not result in such rapid and dramatic changes as some other deficiencies, such as in the case of vitamin A, a deficiency that results in such marked and *irreversible* damage to such a highly

specialized tissue as the lens, should not be considered lightly.

Child's Sleep—Effect of Certain Foods and Beverages on Sleep Motility^{*}

GLENVILLE GIDDINGS, M.D.

Assistant Professor of Medicine, Emory University, Atlanta, Ga.

THE importance of diet both in the treatment of disease and in its prophylaxis is now commonly accepted. The advances made in this field in the deficiency diseases, the vitamins, the anemias, and arthritis, reflect but a few of the problems under investigation. What further etiological factors of disease will be traced to faulty diet and dietary habits is a matter of interesting speculation.

We have attempted a study of a very homely problem. What is the effect of various foods and beverages on sleep? This problem has been of particular interest to us as to its effects on children. When should the school child eat its heaviest meal—at noon or at night? Certainly in the average American home the heaviest meal is served in the evening between 6 and 7 p.m. In most instances the school child has been put to bed within 2 hours after this meal is completed. What effect, if any, does this have on the child's sleep? In many homes immediately before retiring the child (and frequently the adults too) will take some food—a glass of milk or orange juice or a plate of ice cream. What effect does this bedtime food or drink have on the child's sleep? Many have speculated, both advocating and condemning this practice, but, so far as the literature reveals, there has

been no rigid investigation to give an answer. Our sleep studies were begun nearly two years ago at an isolated school in the mountains of North Georgia. These studies are still in the process of completion and this paper is in the nature of a preliminary report. We have used 42 children in making the study, varying in age between 9 and 14 years. The children are equally divided as to sex. So far, we have graphic records of about 90,000 hours of sleep under controlled conditions.

Each child that is used as a subject is examined physically and such laboratory tests as basal metabolism, electrocardiogram, urinalysis, blood count, and examination of stool for intestinal parasites, are made. Children with organic defects were not accepted. Those showing remediable conditions, such as diseased tonsils, teeth, hookworm, and the like, were treated and then admitted. We made every effort to be sure we were dealing with normal children. On account of the isolated location of the sleep laboratory, such extraneous influences as automobiles, street cars, and trains did not constitute a problem. The sleep laboratory itself consisted of two very large halls, each amply accommodating 12 beds—one hall for males and one for females. Beds, springs, mattresses, pillows, and bed clothing were identical for each child. The amount of bed covering was determined, on retiring, by the nurse in

^{*} Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

charge. The children retired each night at 8:30 and arose at 5:30 a.m. Care was taken that all retired at the same minute and lounging on the bed before this time was not allowed.

During the first 3 months of this investigation, as has been previously reported,* the children were observed at 15 minute intervals by the nurses to determine how they were sleeping. It seemed to us that change of position might be used as an index to the character of the child's sleep. For recording this we devised a form using symbols for the various body positions so that the nurses might rapidly fill this in as rounds were made, and the total number of changes of position computed the following morning, thus determining whether or not the child had had a normal or a restless night. It is evident that in using this method of observation only gross changes of position could be determined, that many minor muscular movements occurring under the cover eluded detection. For this reason in September, 1932, we changed to the electrically recording hypnograph.

METHOD AND APPARATUS FOR RECORDING SLEEP MOVEMENTS

The machine which we are using for recording sleep was originally described by Renshaw and Weiss.¹ In brief, the principle involved is as follows: The bed mechanism attached to the bed-spring consists of a perpendicular piece of metal containing alternate inserts of bakelite and brass. A small brass wheel travels up and down this piece which makes or breaks an electric contact with the slightest movement of the individual occupying the bed. This contact is conducted through cables into an adjoining room in which is placed the hypnograph itself. The hypnograph consists of a

battery of 24 stylus pens (one for each bed) which write upon a uniformly travelling roll of paper, 8 inches broad. Two colors of ink are used in the pens, one for the males and another for the females. As this paper passes under the pens it is stamped electrically by a timer at 1 minute intervals, so that at the end of a night's observations this can be ruled out 60 minutes to the hour and each body movement accurately recorded, minute by minute, for the entire 9 hours, or 540 minutes, that the child is in bed. As the contacts are made or broken by the bed mechanism, electro-magnets on each pen of the hypnograph make offsets from the base line on the record. Beside the hypnograph are relay boxes so arranged that if the circuit through any bed ceases functioning properly, the signal lamp will light and remaining burning until the condition is corrected. Thus should an individual leave his bed for any purpose during the night, the relay lamp will at once notify the operator of this fact.

At the end of each night's observations the active minutes, that is, any minute during which a sleeper makes any movement, are counted, hour by hour, and recorded for each of the 24 individuals, the total number of active minutes being entered at the end of the night. From this record the observations are copied daily onto the individual's record.

That we may properly evaluate the measurement of sleep movement as an index to the depth of sleep, let us review briefly the results of some prior investigations.

Kohlschutter² some 70 years ago, using auditory stimuli, showed that the depth of sleep was reached quite early in the night. Later this was confirmed by Michelson.³ These observations and ours seem in general to agree, as certainly in children, at least, sleep is more quiet in the second 30 to 60 minutes after

* Read before the Section on Pediatrics at the Eighty-fourth Annual Session of the American Medical Association, Milwaukee, June, 1933.

a child has retired than at any other part of the night. Canestrini⁴ observed as a criterion of awakening slight movements and changes in the type of breathing. Kussmaul⁵ showed that, in young infants, stimulation by light caused a tightening of the eye lids. Using this as a confirmatory index of the depth of sleep, Renshaw⁶ has recently shown that immediately before and immediately after body movement, the amount of light stimulation necessary to cause lid tightening was very much less than when no sleep movements were present. It is an assumption, therefore, that the depth of sleep is immeasurably lighter at the time that a movement is made. Further work is in progress on this point.

NORMAL SLEEP PATTERN

In an attempt to arrive at what constitutes the normal sleep pattern we used 15 consecutive nights in which the 24 children had followed their normal daily routine. This normal sleep pattern which we used is based on a study of 3,240 hours of normal sleep. Considering the children from an individual standpoint, we can say that, except in a very general way, no two children have the same sleep curve. The first hour in bed is the most active hour and the next most active hour is the last regular hour of sleep. In a vast majority of children the quietest sleep is reached the second 30 to 60 minutes after going to bed. As a concrete example, if a child retires at 8:30 p.m. and arises at 5:30 a.m., it will show more restlessness—more active minutes—between 8:30 and 9:30 p.m. and 4:30 and 5:30 a.m., than in any other 2 hours of the night. Aside from this, generalities cease, and what may be quite normal for one child, may be distinctly abnormal for the second child, assuming both to be normal children. These facts apply equally to males and females.

The graphs presented are plotted on ratio paper. We believe that the trend may be more readily seen by using this method. The hours of sleep are listed at the top of the graph with a scale showing the active number of minutes to the left of the graph: the lower limb of the graph shows the body movements, hour by hour, of the child or children under observation and the upper limb of the graph is a summation of the minute movements throughout the night. The resultant curve we refer to as the child's sleep pattern. Once established this curve rarely varies except with the seasons or the introduction of experimental conditions. We have observed that, as a sex, females are sounder sleepers than males, not only do they get to sleep more quickly, but sleep more quietly throughout the night.

THE EFFECT OF CERTAIN BEVERAGES ON SLEEP

Among other studies made we have collected certain data on the effect of cold water, cold milk, warm water, warm milk, a cold beverage containing 0.6 gr. caffeine, and orange juice. We will present on graphs the group averages both on boys and on girls. Twelve children, equally divided as to sex, were used in each experiment.

It has long been thought that the drinking of certain beverages at bedtime might induce sleep. The administration of a glass of warm milk to neurasthenics on retiring has long been a therapeutic practice. If this beverage does induce sleep, would not the ingestion of the same amount of warm water at the same temperature produce the same result. In each experiment cited the beverage was given at 8:15 p.m. and the children were in bed and the lights out at 8:30. Each experiment was done on 5 consecutive nights. Figure I shows the group average for the boys.

SHOWING EFFECT OF WARM MILK AND WARM WATER ON SLEEP PATTERN

In making an estimate of the significance of the results obtained it seemed wise to adopt the biometric method which is widely used, namely, that of determining the probable error. In explanation of the meaning of the probable error, it may be stated that it has long been a universal custom among biometric workers that the difference (or constant) which is smaller than twice its probable error is probably not significant, whereas the difference (or constant) which is three or more times its probable error is either "certainly" or at least "almost certainly" significant.⁷

In the case of the warm water experiment, the difference in the number of movements, before and after the experiment, was less than three times the probable error in 8.3 per cent of the children, was greater in the same per-
